Preface

The emergence of the concept of a computable function over fifty years ago marked the birth of a new branch of mathematics: its importance may be judged from the fact that it has had applications and implications in fields as diverse as computer science, philosophy and the foundations of mathematics, as well as in many other areas of mathematics itself. This book is designed to be an introduction to the basic ideas and results of computability theory (or recursion theory, as it is traditionally known among mathematicians).

The initial purpose of computability theory is to make precise the intuitive idea of a computable function; that is, a function whose values can be calculated in some kind of automatic or effective way. Thereby we can gain a clearer understanding of this intuitive idea; and only thereby can we begin to explore in a mathematical way the concept of computability as well as the many related ideas such as decidability and effective enumerability. A rich theory then arises, having both positive and negative aspects (here we are thinking of non-computability and undecidability results), which it is the aim of this book to introduce.

We could describe computability theory, from the viewpoint of computer science, as beginning with the question What can computers do \textit{in principle} (without restrictions of space, time or money)?—and, by implication—What are their inherent theoretical limitations? Thus this book is not about real computers and their hardware, nor is it about programming languages and techniques. Nevertheless, our subject matter is part of the theoretical background to the real world of computers and their use, and should be of interest to the computing community.

For the basic definition of computability we have used the ‘idealised computer’ or register machine approach; we have found that this is readily grasped by students, most of whom are aware of the idea of a computer. (We do not, however, assume such an awareness (although it is helpful)

and even less do we assume any practical experience with computers or calculators.) Our approach is mathematically equivalent to the many others that have been discovered, including Turing machines, the favourite of many. (We discuss these equivalences in chapter 3.)

This text grew out of a course given to undergraduates in mathematics and computer science at the University of Hull. The reader envisaged is a mathematics student with no prior knowledge of this subject, or a student of computer science who may wish to supplement his practical expertise with something of the theoretical background to his subject. We have aimed at the second or third year undergraduate level, although the earlier chapters covering the basic theory (chapters 1–7) should be within the grasp of good students in sixth forms, high schools and colleges (and their teachers). The only prerequisites are knowledge of the mathematical language of sets and functions (reviewed in the Prologue) and the ability to follow a line of mathematical reasoning.

The later chapters (8–12) are largely independent of each other. Thus a short introductory course could consist of chapters 1–7 supplemented by selection according to taste from chapters 8–12. It has been our aim in these later chapters to provide an introduction to some of the ramifications and applications of basic computability theory, and thereby provide a stepping stone towards more advanced study. To this end, the final chapter contains a brief survey of possible directions for further study, and some suggestions for further reading. (The two main texts that might be regarded as natural sequels to this one are M. L. Minsky, \textit{Computation: Finite and Infinite Machines}, which would complement the present volume by its broad and comprehensive study of computation (as opposed to computability), and H. Rogers, \textit{Theory of Recursive Functions and Effective Computability}, which provides a more advanced treatment of recursion theory in depth.)

Many people have helped towards the writing of this book. I would first thank John Cleave, who taught me recursive function theory in a graduate course at the University of Bristol in 1966, and introduced me to the register machine approach that I have used here. I have greatly appreciated the sustained interest and encouragement from Stan Wainer (who also made valuable suggestions for the material in chapters 10 and 12) and David Jordan: I thank them. I would also like to thank David Jordan and Dick Epstein for reading a draft of the manuscript and making many valuable comments and corrections. I am grateful to the Cambridge University Press for their interest and advice which has resulted in the emergence of the completed manuscript.
Finally, a big thank you to my wife Mary for her patience and encouragement during the many phases of writing and preparation of this book; her idealism and understanding have been a sustaining influence throughout.

Prologue
Prerequisites and notation

The only prerequisite to be able to read this book is familiarity with the basic notations of sets and functions, and the basic ideas of mathematical reasoning. Here we shall review these matters, and explain the notation and terminology that we shall use. This is mostly standard; so for the reader who prefers to move straight to Chapter 1 and refer back to this prologue only as necessary, we point out that we shall use the word function to mean a partial function in general. We discuss this more fully below.

1. Sets
   Generally we shall use capital letters $A, B, C, \ldots$ to denote sets. We write $x \in A$ to mean that $x$ is a member of $A$, and we write $x \notin A$ to mean that $x$ is not a member of $A$. The notation $\{x : \ldots \}$ where $\ldots \ldots$ is some statement involving $x$ means the set of all objects $x$ for which $\ldots \ldots$ is true. Thus $\{x : x$ is an even natural number$\}$ is the set $\{0, 2, 4, 6, \ldots \}$.

   If $A, B$ are sets, we write $A \subseteq B$ to mean that $A$ is contained in $B$ (or $A$ is a subset of $B$); we use the notation $A \subset B$ to mean that $A \subseteq B$ but $A \neq B$ (i.e. $A$ is a proper subset of $B$). The union of the sets $A, B$ is the set $\{x : x \in A$ or $x \in B$ (or both)$\}$, and is denoted by $A \cup B$; the intersection of $A, B$ is the set $\{x : x \in A$ and $x \in B\}$ and is denoted by $A \cap B$. The difference (or relative complement) of the sets $A, B$ is the set $\{x : x \in A$ and $x \notin B\}$ and is denoted by $A \setminus B$.

   The empty set is denoted by $\emptyset$. We use the standard symbol $\mathbb{N}$ to denote the set of natural numbers $\{0, 1, 2, 3, \ldots \}$. If $A$ is a set of natural numbers (i.e. $A \subseteq \mathbb{N}$) we write $\complement A$ to denote the complement of $A$ relative to $\mathbb{N}$, i.e. $\mathbb{N} \setminus A$. We write $\mathbb{N}^{+}$ for the set of positive natural numbers $\{1, 2, 3, \ldots \}$, and as usual $\mathbb{Z}$ denotes the set of integers.
We write \((x, y)\) to denote the ordered pair of elements \(x\) and \(y\); thus \((x, y) \neq (y, x)\) in general. If \(A, B\) are sets, the Cartesian product of \(A\) and \(B\) is the set \(\{(x, y) : x \in A\text{ and } y \in B\}\), and is denoted by \(A \times B\).

More generally, for elements \(x_1, \ldots, x_n\), we write \((x_1, \ldots, x_n)\) to denote the ordered \(n\)-tuple of \(x_1, \ldots, x_n\); an \(n\)-tuple is often represented by a single boldfaced symbol such as \(x\). If \(A_1, \ldots, A_n\) are sets we write \(A_1 \times \cdots \times A_n\) for the set of \(n\)-tuples \(\{x_1, \ldots, x_n) : x_1 \in A_1\text{ and } x_2 \in A_2\text{ and } \ldots \text{and } x_n \in A_n\}\). The product \(A \times A \times \cdots \times A\) (\(n\) times) is abbreviated by \(A^n\), \(A^1\) means \(A\).

2. Functions

We assume familiarity with the basic idea of a function, and the distinction between a function \(f\) and a particular value \(f(x)\) at any given \(x\) where \(f\) is defined.\(^1\) If \(f\) is a function, the domain of \(f\) is the set \(\{x : f(x)\text{ is defined}\}\), and is denoted \(\text{Dom}(f)\); we say that \(f(x)\) is undefined if \(x \notin \text{Dom}(f)\). The set \(\{f(x) : x \in \text{Dom}(f)\}\) is called the range of \(f\), and is denoted by \(\text{Ran}(f)\). If \(A\) and \(B\) are sets we say that \(f\) is a function from \(A\) to \(B\) if \(\text{Dom}(f) \subseteq A\) and \(\text{Ran}(f) \subseteq B\). We use the notation \(f : A \to B\) to mean that \(f\) is a function from \(A\) to \(B\) with \(\text{Dom}(f) = A\).

A function \(f\) is said to be injective if whenever \(x, y \in \text{Dom}(f)\) and \(x \neq y\), then \(f(x) \neq f(y)\). If \(f\) is injective, then \(f^{-1}\) denotes the inverse of \(f\), i.e., the unique function \(g\) such that \(\text{Dom}(g) = \text{Ran}(f)\) and \(g(f(x)) = x\) for \(x \in \text{Dom}(f)\). A function \(f\) from \(A\) to \(B\) is surjective if \(\text{Ran}(f) = B\).

If \(f : A \to B\), we say that \(f\) is an injection (from \(A\) to \(B\)) if it is injective, and a surjection (from \(A\) to \(B\)) if it is surjective. It is a bijection if it is both an injection and a surjection.

Suppose that \(f\) is a function and \(X\) is a set. The restriction of \(f\) to \(X\), denoted by \(f|X\), is the function with domain \(X \cap \text{Dom}(f)\) whose values for \(x \in X \cap \text{Dom}(f)\) is \(f(x)\). We write \(f|X\) for \(\text{Ran}(f|X)\). If \(Y\) is a set, then the inverse image of \(Y\) under \(f\) is the set \(f^{-1}(Y) = \{x : f(x) \in Y\}\). (Note that this is defined even when \(f\) is not injective.)

If \(f, g\) are functions, we say that \(g\) extends \(f\) if \(\text{Dom}(g) = \text{Dom}(f)\) and \(f(x) = g(x)\) for all \(x \in \text{Dom}(f)\); in short, \(f \subseteq g\). This is written \(f \subseteq g\).

The composition of two functions \(f, g\) is the function whose domain is the set \(\{x : x \in \text{Dom}(g)\text{ and } g(x) \in \text{Dom}(f)\}\), and whose value is \(f(g(x))\) when defined. This function is denoted \(f \circ g\).

We denote by \(f_0\) the function that is defined nowhere; i.e., \(f_0\) has the property that \(\text{Dom}(f_0) = \emptyset\). Clearly \(f_0 = g|\emptyset\) for any function \(g\).

Often in computability we shall encounter functions, or expressions involving functions, that are not always defined. In such situations the following notation is very useful. Suppose that \(\alpha(x)\) and \(\beta(x)\) are expressions involving the variables \(x = (x_1, \ldots, x_n)\). Then we write

\[
\alpha(x) = \beta(x)
\]

to mean that for any \(x\), the expressions \(\alpha(x)\) and \(\beta(x)\) are either both defined, or both undefined, and if defined they are equal. Thus, for example, if \(f, g\) are functions, writing \(f(x) = g(x)\) is another way of saying that \(f = g\), and for any number \(y\), \(f(x) = y\) means that \(f(x)\) is defined and \(f(x) = y\) (since \(y\) is always defined).

Functions of natural numbers For most of this book we shall be concerned with functions of natural numbers; that is, functions from \(\mathbb{N}^n\) to \(\mathbb{N}\) for various \(n\), most commonly \(n = 1\) or \(2\).

A function \(f\) from \(\mathbb{N}^n\) to \(\mathbb{N}\) is called an \(n\)-ary function. The value of \(f\) at an \(n\)-tuple \((x_1, \ldots, x_n) \in \text{Dom}(f)\) is written \(f(x_1, \ldots, x_n)\) or \(f(x)\), if \(x\) represents \((x_1, \ldots, x_n)\). In some texts the phrase partial function is used to describe a function from \(\mathbb{N}^n\) to \(\mathbb{N}\) whose domain is not necessarily the whole of \(\mathbb{N}^n\). For us the word function means partial function. On occasion we will, nevertheless, write partial function to emphasize this fact. A total function from \(\mathbb{N}^n\) to \(\mathbb{N}\) is a function whose domain is the whole of \(\mathbb{N}^n\).

Particularly with number theoretic functions, we shall blur the distinction between a function and its particular values in two fairly standard and unambiguous ways. First we shall allow a phrase such as \("Let \((x_1, \ldots, x_n)\) be a function \ldots\)\) as a means of indicating that \(f\) is an \(n\)-ary function. Second, we shall often describe a function in terms of its general value when this is given by a formula. For instance, \("the function \(x^2\) means \(x \cdot x\)\) is a unary function whose value at any \(x \in \mathbb{N}\) is \(x^2\); similarly, \("the function \(x + y\)\) is the binary function whose value at \((x, y) \in \mathbb{N}^2\) is \(x + y\).

We describe the zero function \(\mathbb{N}^n \to \mathbb{N}\) by \(\theta\); and generally, for \(m \in \mathbb{N}\), we denote the function \(\mathbb{N} \to \mathbb{N}\) whose value is always \(m\) by the boldface symbol \(m\).
3. Relations and predicates

If $A$ is a set, a property $M(x_1, \ldots, x_n)$ that holds (or is true) for some $n$-tuples from $A^*$ and does not hold (or is false) for all other $n$-tuples from $A$ is called an $n$-ary relation or predicate on $A$.\(^2\)

For example, the property $x < y$ is a binary relation (or predicate) on $\mathbb{N}$, $2 < 3$ holds (or is true) whereas $9 < 5$ does not hold (or is false). As another example, any $n$-ary function $f$ from $\mathbb{N}^n$ to $\mathbb{N}$ gives rise to an $(n+1)$-ary predicate $M(x, y)$ given by

$$M(x_1, \ldots, x_n, y) \text{ if and only if } f(x_1, \ldots, x_n) = y.$$  

**Equivalence relations and orders** (The student unfamiliar with these notions may prefer to delay reading this paragraph until it is needed in chapter 9.) In chapter 9 we shall encounter two special kinds of relations on a set $A$.

(a) A binary relation $R$ on a set $A$ is called an equivalence relation if it has the following properties for all $x, y, z \in A$:

(i) (reflexivity) $R(x, x)$;

(ii) (symmetry) if $R(x, y)$ then $R(y, x)$;

(iii) (transitivity) if $R(x, y)$ and $R(y, z)$ then $R(x, z)$.

We think of $R(x, y)$ as saying that $x$ and $y$ are equivalent (in some particular sense). Then we define the equivalence class of $x$ as the set $\{y : R(x, y)\}$ consisting of all things equivalent to $x$.

(b) A binary relation $R$ on a set $A$ is called a partial order if, for all $x, y, z \in A$,

(i) (irreflexivity) not $R(x, x)$;

(ii) (transitivity) if $R(x, y)$ and $R(y, z)$ then $R(x, z)$.

A partial order is usually denoted by the symbol $\leq$, and we write $x \leq y$ rather than $< (x, y)$. A partial order is often defined by first defining $\leq$ (meaning $\leq$ or $=$), with the properties

(i) $x \leq x$;

(ii) if $x \leq y$ and $y \leq x$ then $x = y$;

(iii) $\leq$ is transitive;

and then defining $x < y$ to mean $x \leq y$ and $x \neq y$.

4. Logical notation

Our logical notation and usage will be standard throughout. We use the word "iff" as an abbreviation for if and only if. The symbol $\equiv$ denotes definitional equivalence, while $\Rightarrow$ denotes implies, and $\Leftrightarrow$ denotes implies and is implied by. We use the symbols $\forall, \exists$ to mean 'for all' and 'there exists' in the standard way.

The symbol $\square$ is used in the text to indicate the end of a proof.

5. References

Each chapter is divided into sections, and items in each section are numbered consecutively. A reference such as theorem 1.4 means theorem 1.4 of chapter 5; this is the fourth numbered item of § 5 in that chapter. When referring within a chapter the number of the chapter is omitted. Exercises are included in this system of numbering. Thus exercise 6.1.8(2) means the second exercise of exercises 1.8, found in chapter 6.

Reference to entries in the bibliography is made by citing the author and year of publication of the work referred to.
Computable functions

We begin this chapter with a discussion of the fundamental idea of an algorithm or effective procedure. In subsequent sections we describe the way in which this idea can be made precise using a kind of idealised computer; this lays the foundation for a mathematical theory of computability and computable functions.

1. **Algorithms, or effective procedures**
   
   When taught arithmetic in junior school we all learnt to add and to multiply two numbers. We were not merely taught that any two numbers have a sum and a product – we were given methods or rules for finding sums and products. Such methods or rules are examples of algorithms or effective procedures. Their implementation requires no ingenuity or even intelligence beyond that needed to obey the teacher's instructions.

   More generally, an algorithm or effective procedure is a mechanical rule, or automatic method, or programme for performing some mathematical operation. Some more examples of operations for which easy algorithms can be given are

   \begin{align*}
   (1.1) \quad & (a) \text{ given } n, \text{ finding the } n \text{th prime number,} \\
   & (b) \text{ differentiating a polynomial,} \\
   & (c) \text{ finding the highest common factor of two numbers (the Euclidean algorithm),} \\
   & (d) \text{ given two numbers } x, y \text{ deciding whether } x \text{ is a multiple of } y.
   \end{align*}

   Algorithms can be represented informally as shown in fig. 1a. The input is the raw data or object on which the operation is to be performed (e.g. a polynomial for (1.1) (b), a pair of numbers for (1.1) (c) and (d)) and the output is the result of the operation (e.g. for (1.1) (b), the derived polynomial, and for (1.1) (d), the answer yes or no). The output is produced mechanically by the black box – which could be thought of as a
calculating machine, a computer, or a schoolboy correctly taught—or even a very clever dog trained appropriately. The algorithm is the procedure or method that is carried out by the black box to obtain the output from the input.

When an algorithm or effective procedure is used to calculate the values of a numerical function then the function in question is described by phrases such as effectively calculable, or algorithmically computable, or effectively computable, or just computable. For instance, the functions $xy$, $HCF(x, y) = \text{the highest common factor of } x \text{ and } y$, and $f(n) = \text{the } n\text{th prime number}$, are computable in this informal sense, as already indicated. Consider, on the other hand, the following function:

$$g(n) = \begin{cases} 
1 & \text{if there is a run of exactly } n \text{ consecutive } 7\text{s in the decimal expansion of } \pi, \\
0 & \text{otherwise.}
\end{cases}$$

Most mathematicians would accept that $g$ is a perfectly legitimate function. But is $g$ computable? There is a mechanical procedure for generating successive digits in the decimal expansion of $\pi$, so the following ‘procedure’ for computing $g$ suggests itself.

Given $n$, start generating the decimal expansion of $\pi$, one digit at a time, and watch for 7s. If at some stage a run of exactly $n$ consecutive 7s has appeared, then stop the process and put $g(n) = 1$. If no such sequence of 7s appears put $g(n) = 0$.

The problem with this ‘procedure’ is that, if for a particular $n$ there is no sequence of exactly $n$ consecutive 7s, then there is no stage in the process where we can stop and conclude that this is the case. For all we know at any particular stage, such a sequence of 7s could appear in the part of the expansion of $\pi$ that has not yet been examined. Thus the ‘procedure’ will go on for ever for inputs $n$ such that $g(n) = 0$; so it is not an effective procedure. (It is conceivable that there is an effective procedure for computing $g$ based, perhaps, on some theoretical properties of $\pi$. At the present time, however, no such procedure is known.)

This example pinpoints two features implicit in the idea of an effective procedure—namely, that such a procedure is carried out in a sequence of stages or steps (each completed in a finite time), and that any output should emerge after a finite number of steps.

So far we have described informally the idea of an algorithm, or effective procedure, and the associated notion of computable function. These ideas must be made precise before they can become the basis for a mathematical theory of computability—and non-computability.

We shall make our definitions in terms of a simple ‘idealised computer’ that operates programs. Clearly, the procedures that can be carried out by a real computer are examples of effective procedures. Any particular real computer, however, is limited both in the size of the numbers that it can compute, and in the amount of space available; it is in these respects that our ‘computer’ will be idealised in accordance with the informal idea of an algorithm. The programs for our machine will be finite, and we will require that a completed computation takes only a finite number of steps. Inputs and outputs will be restricted to natural numbers; this is not a significant restriction, since operations involving other kinds of object can be coded as operations on natural numbers. (We discuss this more fully in §5.)

2. The unlimited register machine

Our mathematical idealisation of a computer is called an unlimited register machine (URM); it is a slight variation of a machine first conceived by Shepherdson & Sturgis [1963]. In this section we describe the URM and how it works; we begin to explore what it can do in §3.

The URM has an infinite number of registers labelled $R_1, R_2, R_3, \ldots$, each of which at any moment of time contains a natural number; we denote the number contained in $R_n$ by $r_n$. This can be represented as follows

- $R_1 \quad R_2 \quad R_3 \quad R_4 \quad R_5 \quad R_6 \quad R_7 \quad \ldots$

The contents of the registers may be altered by the URM in response to certain instructions that it can recognise. These instructions correspond to very simple operations used in performing calculations with numbers. A finite list of instructions constitutes a program. The instructions are of four kinds, as follows.
Zero instructions. For each \( n = 1, 2, 3, \ldots \) there is a zero instruction \( Z(n) \). The response of the URM to the instruction \( Z(n) \) is to change the contents of \( R_n \) to 0, leaving all other registers unaltered.

Example Suppose that the URM is in the following configuration

\[
\begin{array}{cccccc}
R_1 & R_2 & R_3 & R_4 & R_5 & R_6 \\
9 & 6 & 5 & 23 & 7 & 0 \\
\end{array}
\]

and obeys the zero instruction \( Z(3) \). Then the resulting configuration is

\[
\begin{array}{cccccc}
R_1 & R_2 & R_3 & R_4 & R_5 & R_6 \\
9 & 6 & 0 & 23 & 7 & 0 \\
\end{array}
\]

The response of the URM to a zero instruction \( Z(n) \) is denoted by \( 0 \rightarrow R_n \) or \( r_n \rightarrow 0 \) (this is read \( r_n \) becomes 0).

Successor instructions. For each \( n = 1, 2, 3, \ldots \) there is a successor instruction \( S(n) \). The response of the URM to the instruction \( S(n) \) is to increase the number contained in \( R_n \) by 1, leaving all other registers unaltered.

Example Suppose that the URM is in the configuration \((*)\) above and obeys the successor instruction \( S(5) \). Then the new configuration is

\[
\begin{array}{cccccc}
R_1 & R_2 & R_3 & R_4 & R_5 & R_6 \\
9 & 6 & 0 & 23 & 8 & 0 \\
\end{array}
\]

The effect of a successor instruction \( S(n) \) is denoted by \( r_n + 1 \rightarrow R_n \), or \( r_n = r_n + 1 \) (\( r_n \) becomes \( r_n + 1 \)).

Transfer instructions. For each \( m = 1, 2, 3, \ldots \) and \( n = 1, 2, 3, \ldots \) there is a transfer instruction \( T(m, n) \). The response of the URM to the instruction \( T(m, n) \) is to replace the contents of \( R_m \) by the number \( r_n \) contained in \( R_n \) (i.e. transfer \( r_n \) into \( R_m \)); all other registers (including \( R_m \)) are unaltered.

Example Suppose that the URM is in the configuration \((**)\) above and obeys the transfer instruction \( T(5, 1) \). Then the resulting configuration is

\[
\begin{array}{cccccc}
R_1 & R_2 & R_3 & R_4 & R_5 & R_6 \\
8 & 6 & 0 & 23 & 8 & 0 \\
\end{array}
\]

The response of the URM to a transfer instruction \( T(m, n) \) is denoted by \( t_m \rightarrow R_n \), or \( r_n := t_m \) (\( r_n \) becomes \( r_m \)).

Jump instructions. In the operation of an informal algorithm there may be a stage when alternative courses of action are prescribed, depending on the progress of the operation up to that stage. In other situations it may be necessary to repeat a given routine several times. The URM is able to reflect such procedures as these using jump instructions; these will allow jumps backwards or forwards in the list of instructions. We shall, for example, be able to use a jump instruction to produce the following response:

'If \( r_2 = r_6 \), go to the 10th instruction in the program; otherwise, go on to the next instruction in the program.'

The instruction eliciting this response will be written \( J(2, 6, 10) \).

Generally, for each \( m = 1, 2, 3, \ldots \), \( n = 1, 2, 3, \ldots \) and \( q = 1, 2, 3, \ldots \) there is a jump instruction \( J(m, n, q) \). The response of the URM to the instruction \( J(m, n, q) \) is as follows. Suppose that this instruction is encountered in a program \( P \). The contents of \( R_m \) and \( R_n \) are compared, but all registers are left unaltered. Then

- If \( r_m = r_n \), the URM proceeds to the \( q \)th instruction of \( P \);
- If \( r_m \neq r_n \), the URM proceeds to the next instruction in \( P \).

If the jump is impossible because \( P \) has less than \( q \) instructions, then the URM stops operation.

Zero, successor and transfer instructions are called arithmetic instructions.

We summarise the response of the URM to the four kinds of instruction in table 1.

**Computation** To perform a computation the URM must be provided with a program \( P \) and an initial configuration—i.e. a sequence \( a_1, a_2, a_3, \ldots \) of natural numbers in the registers \( R_1, R_2, R_3, \ldots \). Suppose that \( P \) consists of \( s \) instructions \( I_1, I_2, \ldots, I_s \). The URM begins the computation by obeying \( I_1 \), then \( I_2, I_3 \), and so on unless a jump
Table 1

<table>
<thead>
<tr>
<th>Type of instruction</th>
<th>Instruction</th>
<th>Response of the URM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zero</td>
<td>Z(n)</td>
<td>Replace $r_e$ by 0, (0 \rightarrow R_m) or (r_e = 0)</td>
</tr>
<tr>
<td>Successor</td>
<td>S(n)</td>
<td>Add 1 to $r_e$, (r_e + 1 \rightarrow R_m) or (r_e = r_e + 1)</td>
</tr>
<tr>
<td>Transfer</td>
<td>T(m, n)</td>
<td>Replace $r_e$ by (r_m), (r_m \rightarrow R_m) or (r_e = r_m)</td>
</tr>
<tr>
<td>Jump</td>
<td>J(m, n, q)</td>
<td>If (r_m = r_e), jump to the (q)th instruction; otherwise go on to the next instruction in the program.</td>
</tr>
</tbody>
</table>

An instruction, say \(J(m, n, q)\), is encountered. In this case the URM proceeds to the instruction prescribed by \(J(m, n, q)\) and the current contents of the registers \(R_m\) and \(R_n\). We illustrate this with an example.

2.1. Example
Consider the following program:

\[
\begin{align*}
I_1 & : J(1, 2, 6) \\
I_2 & : S(2) \\
I_3 & : S(3) \\
I_4 & : J(1, 2, 6) \\
I_5 & : J(1, 1, 2) \\
I_6 & : T(3, 1)
\end{align*}
\]

Let us consider the computation by the URM under this program with initial configuration

\[
\begin{array}{cccccc}
R_1 & R_2 & R_3 & R_4 & R_5 \\
9 & 7 & 0 & 0 & 0 & \ldots
\end{array}
\]

(We are not concerned at the moment about what function this program actually computes; we wish to illustrate the way in which the URM operates programs in a purely mechanical fashion without needing to understand the algorithm that is being carried out.)

We can represent the progress of the computation by writing down the successive configurations that occur, together with the next instruction to be obeyed at the completion of each stage.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Next instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>(9\ 7\ 0\ 0\ 0\ \ldots\</td>
<td>(I_1)</td>
</tr>
<tr>
<td>(9\ 7\ 0\ 0\ 0\</td>
<td>I_2 ) (since (r_1 \neq r_2)</td>
</tr>
<tr>
<td>(9\ 8\ 0\ 0\ 0\</td>
<td>I_3 )</td>
</tr>
<tr>
<td>(9\ 8\ 1\ 0\ 0\</td>
<td>I_4 )</td>
</tr>
<tr>
<td>(9\ 8\ 1\ 0\ 0\</td>
<td>I_5 ) (since (r_1 \neq r_2)</td>
</tr>
<tr>
<td>(9\ 8\ 1\ 0\ 0\</td>
<td>I_6 ) (since (r_1 = r_1)</td>
</tr>
</tbody>
</table>

and so on. (We shall continue this computation later.)

We can describe the operation of the URM under a program \(P = I_1, I_2, \ldots, I_n\) in general as follows. The URM starts by obeying instruction \(I_1\). At any future stage in the computation, suppose that the URM is obeying instruction \(I_k\). Then having done so it proceeds to the next instruction in the computation, defined as follows:

- if \(I_k\) is not a jump instruction, the next instruction is \(I_{k+1}\);
- if \(I_k = J(m, n, q)\) the next instruction is \(I_{k+1} = I_q\) if \(r_m = r_n\) \(\), otherwise \(I_{k+1}\).

where \(r_m, r_n\) are the current contents of \(R_m\) and \(R_n\).

The URM proceeds thus as long as possible; the computation stops when, and only when, there is no next instruction, i.e., if the URM has just obeyed instruction \(I_k\) and the 'next instruction in the computation' according to the above definition is \(I_e\), where \(e > s\). This can happen in the following ways:

(i) if \(k = s\) (the last instruction in \(P\) has been obeyed) and \(I_s\) is an arithmetic instruction,
(ii) if \(I_e = J(m, n, q), r_m = r_n\) and \(q > s\),
(iii) if \(I_e = J(m, n, q), r_m \neq r_n\) and \(k = s\).

We say then that the computation stops after instruction \(I_s\); the final configuration is the sequence \(r_1, r_2, r_3, \ldots,\) the contents of the registers at this stage.
Let us now continue the computation begun in example 2.1.

Example 2.1 (continued)

</tr>
</tbody>
</table>

Final configuration: 2 9 2 0 0

I₇: STOP.

This computation stops as indicated because there is no seventh instruction in the program.

2.2. Exercise

Carry out the computation under the program of example 2.1 with initial configuration 8, 4, 2, 0, 0, ...

The essence of a program and the progress of computations under it is often conveniently described informally using a flow diagram. For example, a flow diagram representing the program of example 2.1 is given in fig. 1b. (We have indicated alongside the flow diagram the typical configuration of the registers at various stages in a computation.) Note the convention that tests or questions (corresponding to jump instructions) are placed in diamond shaped boxes.

The translation of this flow diagram into the program of exercise 2.1 is almost self-explanatory. Notice that the backwards jump on answer 'No' to the second question "r₁ = r₅?" is achieved by the fifth instruction J(1, 1, 2) which is an unconditional jump: we always have r₁ = r₅, so this instruction causes a jump to I₂ whenever it is encountered.

When writing a program to perform a given procedure it is often helpful to write an informal flow diagram as an intermediate step: the translation of a flow diagram into a program is then usually routine.

Fig. 1b. Flow diagram for the program of example 2.1.

</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>y+k</td>
<td>z+k</td>
</tr>
</tbody>
</table>

After k cycles round the loop in the program:

If x = y + k:

r₂ → R₁

STOP

There are, of course, computations that never stop: for example, no computation under the simple program S(1), J(1, 1, 1) ever stops. Computation under this program is represented by the flow diagram in fig. 1c. The jump instruction invariably causes the URM to return, or loop back, to the instruction S(1).

There are more sophisticated ways in which a computation may run for ever, but always this is caused essentially by the above kind of repetition or looping back in the execution of the program.
2.3 Exercise

Show that the computation under the program of example 2.1 with initial configuration 2, 3, 0, 0, 0, 0, 0, 0, 0 never stops.

The question of deciding whether a particular computation eventually stops or not is one to which we will return later.

Some notation will help us now in our discussion. Let \( a_1, a_2, a_3, \ldots \) be an infinite sequence from \( \mathbb{N} \) and let \( P \) be a program; we will write

(i) \( P(a_1, a_2, a_3, \ldots) \) for the computation under \( P \) with initial configuration \( a_1, a_2, a_3, \ldots \);

(ii) \( P(a_1, a_2, a_3, \ldots) \downarrow \) to mean that the computation \( P(a_1, a_2, a_3, \ldots) \) eventually stops;

(iii) \( P(a_1, a_2, a_3, \ldots) \uparrow \) to mean that the computation \( P(a_1, a_2, a_3, \ldots) \) never stops.

In most initial configurations that we shall consider, all but finitely many of the \( a_i \) will be 0. Thus the following notation is useful. Let \( a_1, a_2, \ldots, a_n \) be a finite sequence of natural numbers; we write

(iv) \( P(a_1, a_2, \ldots, a_n) \) for the computation

\[ P(a_1, a_2, \ldots, a_n, 0, 0, 0, \ldots) \]

Hence

(v) \( P(a_1, a_2, \ldots, a_n) \downarrow \) means that \( P(a_1, a_2, \ldots, a_n, 0, 0, 0, \ldots) \downarrow \);

(vi) \( P(a_1, a_2, \ldots, a_n) \uparrow \) means that \( P(a_1, a_2, \ldots, a_n, 0, 0, 0, \ldots) \uparrow \).

Often a computation that stops is said to converge, and one that never stops is said to diverge.

3. URM-computable functions

Suppose that \( f \) is a function from \( \mathbb{N}^n \) to \( \mathbb{N} \) \( (n \geq 1) \); what does it mean to say that \( f \) is computable by the URM? It is natural to think in terms of computing a value \( f(a_1, \ldots, a_n) \) by means of a program \( P \) on initial configuration \( a_1, a_2, \ldots, a_n, 0, 0, 0, \ldots \). That is, we consider computations of the form \( P(a_1, a_2, \ldots, a_n) \). If any such computation stops, we need to have a single number that we can regard as the output or result of the computation; we make the convention that this is the number \( r_i \) finally contained in \( R_i \). The final contents of the other registers can be regarded as rough work or jottings, that can be ignored once we have the desired result in \( R_i \).

Since a computation \( P(a_1, \ldots, a_n) \) may not stop, we can allow our definition of computability to apply to functions \( f \) from \( \mathbb{N}^n \) to \( \mathbb{N} \) whose domain may not be all of \( \mathbb{N}^n \); i.e., partial functions. We shall require that the relevant computations stop (and give the correct result!) precisely for inputs from the domain of \( f \). Thus we make the following definitions.

3.1 Definitions

Let \( f \) be a partial function from \( \mathbb{N}^n \) to \( \mathbb{N} \).

(a) Suppose that \( f \) is a program, and let \( a_1, a_2, \ldots, a_n, b \in \mathbb{N} \).

(i) The computation \( P(a_1, a_2, \ldots, a_n) \) converges to \( b \) if \( P(a_1, a_2, \ldots, a_n) \downarrow \) and in the final configuration \( b \) is in \( R_i \). We write this \( P(a_1, a_2, \ldots, a_n) \downarrow b \);

(ii) \( f \) is a URM-computes \( b \) if, for every \( a_1, \ldots, a_n \), \( P(a_1, a_2, \ldots, a_n) \downarrow b \) if and only if \( (a_1, \ldots, a_n) \in \text{Dom}(f) \) and \( f(a_1, \ldots, a_n) = b \). (In particular, this means that \( P(a_1, a_2, \ldots, a_n) \downarrow \) if and only if \( (a_1, \ldots, a_n) \in \text{Dom}(f) \).

(b) The function \( f \) is URM-computable if there is a program that URM-computes \( f \).

The class of URM-computable functions is denoted by \( \mathcal{C}_n \); from now on we shall use the term computable to mean URM-computable, except in chapter 3 where other notions of computability are discussed.

We now consider some easy examples of computable functions.

3.2 Examples

(a) \( x + y \).

We obtain \( x + y \) by adding 1 to \( x \) (using the successor instruction) \( y \) times. A program to compute \( x + y \) must begin on initial configuration \( x, y, 0, 0, 0, 0, \ldots \); our program will keep adding 1 to \( x \) as a counter to keep a record of how many times \( r_i \) is thus increased. A typical configuration during the computation is

\[
\begin{array}{c|c|c|c|c|c|c}
R_1 & R_2 & R_3 & R_4 & R_5 \\
\hline
x+k & y & k & 0 & 0 & \ldots
\end{array}
\]
The program will be designed to stop when \( k = y \), leaving \( x + y \) in \( R_3 \) as required.

The procedure we wish to embody in our program is represented by the flow diagram in fig. 1d. A program that achieves this is the following:

\[
\begin{align*}
I_1 & : J(3, 2, 5) \leftarrow \\
I_2 & : S(1) \\
I_3 & : S(3) \\
I_4 & : J(1, 1, 1) \\
\end{align*}
\]

(The dotted arrow, which is not part of the program, is to indicate to the reader that the final instruction has the effect of always jumping back to the first instruction.) Note that the stop has been achieved by a jump instruction to \( I_5 \) which does not exist. Thus, \( x + y \) is computable.

**Fig. 1d. Flow diagram for addition (example 3.2(a)).**

\[ k = y, \quad r_1 = r_1 + 1 \]

\[ k = k + 1, \quad r_3 = r_3 + 1 \]

\[ x = k + 1; \text{if so, the required result is } k; \text{ otherwise increase both counters by } 1, \text{ and check again.} \]

A program that carries out this procedure is the following:

\[
\begin{align*}
I_1 & : J(1, 4, 9) \\
I_2 & : S(3) \\
I_3 & : J(1, 3, 7) \\
I_4 & : S(2) \\
I_5 & : S(3) \\
I_6 & : J(1, 1, 3) \\
I_7 & : T(2, 1) \\
\end{align*}
\]

Thus the function \( x - 1 \) is computable.

**Fig. 1c. Flow diagram for \( x - 1 \) (example 3.2(b)).**

\[ x = 0? \]

\[ r_1 = 0? \]

\[ x = k + 1; \text{if so, the required result is } k; \text{ otherwise increase both counters by } 1, \text{ and check again.} \]

A typical configuration during a computation will be

\[
\begin{array}{cccc}
R_1 & R_2 & R_3 & R_4 \\
\hline
x & k & k + 1 & 0 \\
\end{array}
\]
(c) \[ f(x) = \begin{cases} \frac{x}{2} & \text{if } x \text{ is even}, \\ \text{undefined} & \text{if } x \text{ is odd}. \end{cases} \]

In this example, \( \text{Dom}(f) = \mathbb{E} \) (the even natural numbers) so we must ensure that our program does not stop on odd inputs.

A procedure for computing \( f(x) \) is as follows. Run two counters, containing \( k \) and \( 2k \) for \( k = 0, 1, 2, 3, \ldots \); for successive values of \( k \), check whether \( x = 2k \); if so, the answer is \( k \); otherwise increase \( k \) by one, and repeat. If \( x \) is odd, this procedure will clearly continue for ever.

The typical configuration will be

\[
\begin{array}{cccc}
R_1 & R_2 & R_3 & R_4 \\
\hline
x & 2k & k & 0 & \ldots \\
\end{array}
\]

with \( k = 0 \) initially. A flow diagram for the above process is given in fig. 1f.

Fig. 1f. Flow diagram for example 3.2(c)).

A program that executes it is

\[
\begin{align*}
I_1 & : J(1, 2, 6) \\
I_2 & : S(3) \\
I_3 & : S(2) \\
I_4 & : S(2) \\
I_5 & : J(1, 1, 1) \\
I_6 & : T(3, 1)
\end{align*}
\]

Hence \( f \) is computable.

Note. The programs in these examples are in no sense the only programs that will compute the functions in question.

Given any program \( P \) (i.e. any finite list of instructions), and \( n \geq 1 \), by thinking of the effect of \( P \) on initial configurations of the form \( a_1, a_2, \ldots, a_n, 0, 0, \ldots \) we see that there is a unique \( n \)-ary function that \( P \) computes, denoted by \( f^P_n \). From the definition it is clear that

\[
\begin{align*}
f^P_n(a_1, \ldots, a_n) &= \begin{cases} 
\text{the unique } b \text{ such that } P(a_1, \ldots, a_n) \downarrow b, \\
\text{undefined, if } P(a_1, \ldots, a_n) \uparrow.
\end{cases}
\end{align*}
\]

In a later chapter we shall consider the problem of determining \( f^P_n \) for any given program \( P \).

It is clear that a particular computable function can be computed by many different programs; for instance, any program can be altered by adding instructions that have no effect. Less trivially, there may be different informal methods for calculating a particular function, and when formalised as programs these would give different programs for the same function. In terms of the notation we have introduced, we can have different programs \( P_1 \) and \( P_2 \), with \( f^P_1 = f^P_2 \) for some (or all) \( n \). Later we shall consider the problem of deciding whether or not two programs compute the same functions.

3.3 Exercises

1. Show that the following functions are computable by devising programs that will compute them.

(a) \( f(x) = \begin{cases} 0 & \text{if } x = 0, \\
1 & \text{if } x \neq 0. \end{cases} \)

(b) \( f(x) = 5 \)

(c) \( f(x, y) = \begin{cases} 0 & \text{if } x = y, \\
1 & \text{if } x \neq y. \end{cases} \)
4. Decidable predicates and problems

In mathematics a common task is to decide whether numbers possess a given property. For instance, the task described in (1.1) (d) is to decide, given numbers \( x, y \), whether they have the property that \( x \) is a multiple of \( y \). An algorithm for this operation would be an effective procedure that on inputs \( x, y \) gives output Yes or No. If we adopt the convention that 1 means Yes, and 0 means No, then the operation amounts to calculation of the function

\[
f(x, y) = \begin{cases} 1 & \text{if } x \text{ is a multiple of } y, \\ 0 & \text{if } x \text{ is not a multiple of } y. \end{cases}
\]

Thus we can say that the property or predicate ‘\( x \) is a multiple of \( y \)’ is algorithmically or effectively decidable, or just decidable if this function \( f \) is computable.

Generally, suppose that \( M(x_1, x_2, \ldots, x_n) \) is an \( n \)-ary predicate of natural numbers. The characteristic function \( c_M(x) \) (setting \( x = (x_1, \ldots, x_n) \)) is given by

\[
c_M(x) = \begin{cases} 1 & \text{if } M(x) \text{ holds}, \\ 0 & \text{if } M(x) \text{ doesn’t hold}. \end{cases}
\]

4.1 Definition

The predicate \( M(x) \) is decidable if the function \( c_M \) is computable; \( M(x) \) is undecidable if \( M(x) \) is not decidable.

4.2 Examples

The following predicates are decidable:
(a) ‘\( x \neq y \)’; the function \( f \) of exercise 3.3 (1c) is the characteristic function of this predicate.
(b) ‘\( x = 0 \)’; the characteristic function is given by

\[
g(x) = \begin{cases} 1 & \text{if } x = 0, \\ 0 & \text{if } x \neq 0. \end{cases}
\]

The following simple program computes \( g \):

\[
J(1, 2, 3) \\
J(1, 1, 4) \\
S(2) \\
T(2, 1)
\]

(c) ‘\( x \) is a multiple of \( y \)’; it is possible to write a program for the characteristic function, but this would be somewhat lengthy and complicated. A simpler demonstration that this predicate is decidable will emerge from the next chapter, where techniques for generating more complex computable functions are developed.

Note that when discussing decidability (or undecidability) we are always concerned with the computability (or non-computability) of total functions.

In the context of decidability, properties or predicates are sometimes described as problems. Thus we might say that the problem ‘\( x \neq y \)’ is decidable. In chapter 6 we will study undecidable problems.

4.3 Exercise

Show that the following predicates are decidable.
(a) ‘\( x < y \)’.
(b) ‘\( x \neq 3 \)’.
(c) ‘\( x \) is even’.

5. Computability on other domains

Since the URM handles only natural numbers, our definition of computability and decidability applies only to functions and predicates
of natural numbers. These notions are easily extended to other kinds of object (e.g., integers, polynomials, matrices, etc.) by means of coding, as follows.

A coding of a domain $D$ of objects is an explicit and effective injection $\alpha : D \rightarrow \mathbb{N}$. We say that an object $d \in D$ is coded by the natural number $\alpha(d)$. Suppose now that $f$ is a function from $D$ to $D$; then $f$ is naturally coded by the function $f^\alpha$ from $\mathbb{N}$ to $\mathbb{N}$ that maps the code of an object $d \in \text{Dom}(f)$ to the code of $f(d)$. Explicitly we have

$$f^\alpha = \alpha \circ f \circ \alpha^{-1}.$$

Now we may extend the definition of URM-computability to $D$ by saying that $f$ is computable if $f^\alpha$ is a computable function of natural numbers.

5.1 Example
Consider the domain $\mathbb{Z}$. An explicit coding is given by the function $\alpha$ where

$$\alpha(n) = \begin{cases} 2n & \text{if } n \geq 0, \\ -2n+1 & \text{if } n < 0. \end{cases}$$

Then $\alpha^{-1}$ is given by

$$\alpha^{-1}(m) = \begin{cases} \frac{1}{2}m & \text{if } m \text{ is even}, \\ -\frac{1}{2}(m+1) & \text{if } m \text{ is odd}. \end{cases}$$

Consider now the function $x - 1$ on $\mathbb{Z}$; if we call this function $f$, then $f^\alpha : \mathbb{N} \rightarrow \mathbb{N}$ is given by

$$f^\alpha(x) = \begin{cases} 1 & \text{if } x = 0 \text{ (i.e., } x = \alpha(0)), \\ x-2 & \text{if } x > 0 \text{ and } x \text{ is even (i.e., } x = \alpha(n), n > 0), \\ x+2 & \text{if } x \text{ is odd (i.e., } x = \alpha(n), n < 0). \end{cases}$$

It is a routine exercise to write a program that computes $f^\alpha$; hence $x - 1$ is a computable function on $\mathbb{Z}$.

The definitions of computable $n$-ary function on a domain $D$ and decidable predicate on $D$ are obtained by the obvious extension of the above idea.

5.2 Exercises
1. Show that the function $2x$ on $\mathbb{Z}$ is computable.
2. Show that the predicate '$x \geq 0$' is a decidable predicate on $\mathbb{Z}$.

2 Generating computable functions

In this chapter we shall see that various methods of combining computable functions give rise to other computable functions. This will enable us to show quite rapidly that many commonly occurring functions are computable, without writing a program each time—a task that would be rather laborious and tedious.

1. The basic functions
First we note that some particularly simple functions are computable; from these base functions (defined in lemma 1.1 below) we shall then build more complicated computable functions using the techniques developed in subsequent sections.

1.1. Lemma
The following basic functions are computable:
(a) the zero function $0: \mathbb{N} \rightarrow \mathbb{N}$ such that $0(x) = 0$ for all $x$;
(b) the successor function $s + 1$;
(c) for each $n \geq 1$ and $1 \leq i \leq n$, the projection function $U^i_n$ given by $U^i_n(x_1, x_2, \ldots, x_n) = x_i$.

Proof. These functions correspond to the arithmetic instructions for the URM. Specifically, programs are as follows:
(a) $0$: program $Z(1)$;
(b) $s + 1$: program $S(1)$;
(c) $U^i_n$: program $T(i, 1)$. □

2 Joining programs together
In each of §§2-5 below we need to write programs that incorporate other programs as subprograms or subroutines. In this section we deal with some technical matters so as to make the program writing of later sections as straightforward as possible.
A simple example of program building is when we have programs \( P \) and \( Q \), and we wish to write a program for the composite procedure: first do \( P \), and then do \( Q \). Our instinct is to simply write down the instructions in \( P \) followed by the instructions in \( Q \). But there are two technical points to consider.

Suppose that \( P = I_1, I_2, \ldots, I_s \). A computation under \( P \) is completed when the 'next instruction for the computation' is \( I_v \) for some \( v > s \). We then require the computation under our composite program to proceed to the first instruction of \( Q \). This will happen automatically if \( v = s + 1 \), but not otherwise. Thus for building composite programs we must confine our attention to programs that invariably stop because the next instruction is \( I_{s+1} \). Such programs are said to be in standard form. Clearly it is only jump instructions that can cause a program to stop in non-standard fashion. Thus we have the following definition.

2.1. **Definition**

A program \( P = I_1, I_2, \ldots, I_s \) is in standard form if, for every jump instruction \( J(m, n, q) \) in \( P \) we have \( q < s + 1 \).

**Examples.** In examples 1-3.2 the programs for (a) and (c) are in standard form, whereas the program in (b) is not.

Insisting on standard form if necessary is no restriction, as we now see.

2.2. **Lemma**

For any program \( P \) there is a program \( P^* \) in standard form such that any computation under \( P^* \) is identical to the corresponding computation under \( P \), except possibly in the manner of stopping. In particular, for any \( a_1, \ldots, a_n, b \),

\[
P(a_1, \ldots, a_n) \downarrow b \quad \text{if and only if} \quad P^*(a_1, \ldots, a_n) \downarrow b.
\]

and hence \( f_P^* = f_P^* \) for every \( n > 0 \).

**Proof.** Suppose that \( P = I_1, I_2, \ldots, I_s \). To obtain \( P^* \) from \( P \) simply change the jump instructions so that all jump stops occur because the jump is to \( I_{s+1} \). Explicitly, put \( P^* = f_1, I_1', \ldots, I_s' \) where

- if \( I_k \) is not a jump instruction, then \( I_k' = I_k \);
- if \( I_k = J(m, n, q) \), then \( I_k' = J(m, n, q+1) \) if \( q < s + 1 \),

Then clearly \( P^* \) is as required.  

Let us assume now that the programs \( P \) and \( Q \) are in standard form. The second problem when joining \( P \) and \( Q \) concerns the jump instructions in \( Q \). A jump \( J(m, n, q) \) occurring in \( Q \) commands a jump to the \( q \)th instruction of \( Q \) if \( r_n = r_m \). But the \( q \)th instruction of \( Q \) will become the \( s + q \)th instruction in the composite program; thus each jump \( J(m, n, q) \) in \( Q \) must be modified to become \( J(m, n, s + q) \) in the composite program if the sense is to be preserved.

Now without any further worry we can define the \emph{join} or concatenation of two programs in standard form:

2.3. **Definition**

Let \( P \) and \( Q \) be programs of lengths \( s \) and \( t \) respectively, in standard form. The \emph{join} or concatenation of \( P \) and \( Q \), written \( PQ \) or \( PQ \), is the program \( I_1, I_2, \ldots, I_n, I_{n+1}, \ldots, I_{n+t} \), where \( P = I_1, \ldots, I_n \) and the instructions \( I_{n+1}, \ldots, I_{n+t} \) are the instructions of \( Q \) with each jump \( J(m, n, q) \) replaced by \( J(m, n, s + q) \).

With this definition it is clear that the effect of \( PQ \) is as desired: any computation under \( PQ \) is identical to the corresponding computation under \( P \) followed by the computation under \( Q \) whose initial configuration is the final configuration from the computation under \( P \).

There are two further considerations before we can proceed to the major tasks of this chapter. Suppose that we wish to compose a program \( Q \) having a given program \( P \) as a subroutine. To write \( Q \) it is often important to be able to find some registers that are unaffected by computations under \( P \). This can be done as follows.

Since \( P \) is finite, there is a smallest number \( u \) such that none of the registers \( R_v \) for \( v > u \) is mentioned in \( P \); i.e. if \( Z(n) \), or \( S(n) \), or \( T(n, m) \), or \( J(m, n, q) \) is an instruction in \( P \), then \( m, n = u \). Clearly, during any computation under \( P \), the contents of \( R_v \) for \( v > u \) remain unaltered, and have no effect on the values of \( r_1, r_2, \ldots, r_u \). Thus when writing our new program \( Q \) the registers \( R_v \), for \( v > u \) can be used, for example, to store information without affecting any computation under the subroutine \( P \). We denote the number \( u \) by \( r(P) \).

Finally, we introduce some notation that will greatly simplify the main proofs of this chapter. Suppose that \( P \) is a program in standard form designed to compute a function \( f(x_1, \ldots, x_n) \). Often when using \( P \) as a
3. **Substitution**

A common way of manufacturing new functions from old is to substitute functions into other functions, otherwise known as composition of functions. In the following theorem we show that when this process is applied to computable functions, the resulting functions are also computable. In short, we say that φ is closed under the operation of substitution.

3.1. **Theorem**

Suppose that \( f(y_1, \ldots, y_k) \) and \( g_1(x), \ldots, g_k(x) \) are computable functions, where \( x = (x_1, \ldots, x_n) \). Then the function \( h(x) \) given by

\[
h(x) = f(g_1(x), \ldots, g_k(x))
\]

is computable.

(Note. \( h(x) \) is defined if and only if \( g_1(x), \ldots, g_k(x) \) are all defined and \( (g_1(x), \ldots, g_k(x)) \in \text{Dom}(f) \); thus, if \( f \) and \( g_1, \ldots, g_k \) are all total functions, then \( h \) is total.)

**Proof.** Suppose that \( F, G_1, \ldots, G_k \) are programs in standard form which compute \( f, g_1, \ldots, g_k \) respectively. We will write a program \( H \) that embodies the following natural procedure for computing \( h \). Given \( x \), use the programs \( G_1, \ldots, G_k \) to compute in succession \( g_1(x), g_2(x), \ldots, g_k(x) \), making a note of these values as they are obtained. Then use the program \( F \) to compute \( f(g_1(x), \ldots, g_k(x)) \).

We must take a little care to avoid losing information needed at later stages in the procedure, namely \( x \) and those values \( g_i(x) \) already obtained. Putting \( m = \max(n, k, \rho(F), \rho(G_1), \ldots, \rho(G_k)) \), we shall begin by storing \( x \) in \( R_{m+1}, \ldots, R_{m+n} \); the registers \( R_{m+n+1}, \ldots, R_{m+n+k} \) will be used to store the values \( g_i(x) \) as they are computed for \( i = 1, 2, \ldots, k \). These registers are completely ignored by computations under \( F, G_1, \ldots, G_k \). A typical configuration during computation under \( H \) will be

<table>
<thead>
<tr>
<th>( R_1 \ldots R_m )</th>
<th>( R_{m+1} \ldots R_{m+n} )</th>
<th>( R_{m+n+1} \ldots R_{m+n+k} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x )</td>
<td>( g_1(x) )</td>
<td>( g_2(x) )</td>
</tr>
</tbody>
</table>

An informal flow diagram for computing \( h(x) \) is given in fig. 2b. This is easily translated into the following program \( H \) that computes \( h \):

---

Fig. 2a. Flow diagram for \( P[l_1, l_n \rightarrow l] \).

START

Transfer from \( R_{i_1}, \ldots, R_{i_n} \) to \( R_{j_1}, \ldots, R_{j_n} \)

Clear \( R_{j_1}, \ldots, R_{j_n} \)

\( f(x) \rightarrow R_n \) (using \( P \))

STOP
Clearly a computation $H(x)$ will stop if and only if each computation $G_i(x)$ stops (1 ≤ i ≤ k) and the computation $F(g_i(x), \ldots, g_k(x))$ stops, which is exactly as required.

New functions can be obtained from any given function by rearranging or identifying its variables, or by adding new dummy variables; for instance, from a function $f(y_1, y_2)$ we can obtain

- $h_1(x_1, x_2) = f(x_2, x_1)$ (rearrangement),
- $h_2(x) = f(x, x)$ (identification),
- $h_3(x_1, x_2, x_3) = f(x_3, x_2)$ (adding dummy variables).

The following application of theorem 3.1 shows that any of these operations (or a combination of them) transforms computable functions into computable functions.

### 3.2. Theorem

Suppose that $f(y_1, \ldots, y_n)$ is a computable function and that $x_1, x_2, \ldots, x_n$ is a sequence of $k$ of the variables $x_1, \ldots, x_n$ (possibly with repetitions). Then the function $h$ given by

$$h(x_1, \ldots, x_n) = f(x_1, \ldots, x_n)$$

is computable.

**Proof.** Writing $x = (x_1, \ldots, x_n)$ we have that

$$h(x) = f(U^1(x), U^2(x), \ldots, U^n(x))$$

which is computable, by Lemma 1.1(c) and theorem 3.1.

Using this result we can see that theorem 3.1 also holds when the functions $g_1, \ldots, g_k$ substituted into $f$ are not necessarily functions of all of the variables $x_1, \ldots, x_n$, as in the following example.

### 3.3. Example

The function $f(x_1, x_2, x_3) = x_1 + x_2 + x_3$ is computable; this can be deduced from the fact that $x + y$ is computable (example 1-3.2(a)), by substituting $x_1 + x_2$ for $x$, and $x_3$ for $y$ in $x + y$. 

![Diagram](image-url)
3.4. Exercises
1. Without writing any programs, show that for every $m \in \mathbb{N}$ the following functions are computable:
   (a) $m$ (recall that $m(x) = m$, for all $x$).
   (b) $mx$.
2. Suppose that $f(x, y)$ is computable, and $m \in \mathbb{N}$. Show that the function
   $$ h(x) = f(x, m) $$
   is computable.
3. Suppose that $g(x)$ is a total computable function. Show that the predicate $M(x, y)$ given by
   $$ M(x, y) = 'g(x) = y' $$
   is decidable.

4. Recursion

Recursion is a method of defining a function by specifying each of its values in terms of previously defined values, and possibly using other already defined functions.

To be precise, suppose that $f(x)$ and $g(x, y, z)$ are functions (not necessarily total or computable). Consider the following 'definition' of a new function $h(x, y)$:

$$ h(x, 0) = f(x), $$
$$ h(x, y + 1) = g(x, y, h(x, y)). $$

At first sight this may seem a little dubious as a definition, for in the second line it appears that $h$ is being defined in terms of itself - a circular definition! However, with a little thought we can convince ourselves that this is a valid definition: to find the value of $h(x, 3)$ for instance, first find $h(x, 0)$ using (4.1)(i); then, knowing $h(x, 0)$, use (4.1)(ii) to obtain $h(x, 1)$; similarly, obtain $h(x, 2)$ and finally $h(x, 3)$ by further applications of (4.1)(ii). Thus, circularity is avoided by thinking of the values of $h(x, y)$ as being defined one at a time, always in terms of a value already obtained.

A function $h$ defined thus is said to be defined by recursion from the functions $f$ and $g$; the equations 4.1 are known as recursion equations. Unless both $f$ and $g$ are total, then $h$ as defined by (4.1) may not be total; the domain of $h$ will satisfy the conditions

$$ (x, 0) \in \text{Dom}(h) \quad \text{iff} \quad x \in \text{Dom}(f), $$
$$ (x, y + 1) \in \text{Dom}(h) \quad \text{iff} \quad (x, y) \in \text{Dom}(h) \quad \text{and} \quad (x, y, h(x, y)) \in \text{Dom}(g). $$

Let us summarise the above discussion in a theorem, whose proof we omit.

4.2. Theorem
Let $x = (x_1, \ldots, x_n)$, and suppose that $f(x)$ and $g(x, y, z)$ are functions; then there is a unique function $h(x, y)$ satisfying the recursion equations

$$ h(x, 0) = f(x), $$
$$ h(x, y + 1) = g(x, y, h(x, y)). $$

Note. When $n = 0$ (i.e. the parameters $x$ do not appear) the recursion equations take the form

$$ h(0) = a, $$
$$ h(y + 1) = g(y, h(y)). $$

where $a \in \mathbb{N}$.

4.3. Examples
(a) Addition: for any $x, y$ we have

$$ x + 0 = x, $$
$$ x + (y + 1) = (x + y) + 1. $$

Thus addition (i.e. the function $h(x, y) = x + y$) is defined by recursion from the functions $f(x) = x$ and $g(x, y, z) = z + 1$.

(b) $y!$: with the convention that $0! = 1$, we have that

$$ 0! = 1, $$
$$ (y + 1)! = y!(y + 1). $$

Thus the function $y!$ is defined by recursion from 1 and the function $g(y, z) = z(y + 1)$.

There are forms of definition by recursion that are more general than the one we have discussed; we shall encounter an example of this in §5, and a fuller discussion of this topic is included in chapter 10. In contexts
where general kinds of recursion are being considered, the particularly simple kind of definition given by (4.1) is called primitive recursion.

Many commonly occurring functions have easy definitions by (primitive) recursion, so for establishing computability the next theorem is extremely useful. Briefly, it shows that $\mathcal{C}$ is closed under definition by recursion.

4.4. Theorem

Suppose that $f(x)$ and $g(x,y,z)$ are computable functions, where $x = (x_1, \ldots, x_n)$, then the function $h(x,y)$ obtained from $f$ and $g$ by recursion is computable.

Proof. Let $F$ and $G$ be programs in standard form which compute the functions $f(x)$ and $g(x,y,z)$. We will devise a program $H$ for the function $h(x,y)$ given by the recursion equations 4.1. Given an initial configuration $x_1, \ldots, x_n, y, 0, 0, 0, \ldots$ $H$ will first compute $h(x,0)$ (using $F$); then, if $y \neq 0$, $H$ will use $G$ to compute successively $h(x,1)$, $h(x,2), \ldots, h(x,y)$, and then stop.

Let $m = \max(n+2, \rho(F), \rho(G))$; we begin by storing $x, y$ in $R_{n+1}, \ldots, R_{m+3}$; the next two registers will be used to store the current value of the numbers $k$ and $h(x,k)$ for $k = 0, 1, 2, \ldots$. Writing $t$ for $m+n$, a typical configuration during the procedure will thus be

\begin{center}
\begin{tabular}{cccc}
$R_1$ & $\ldots$ & $x$ & $y$ & $k$ & $h(x,k)$ & $\ldots$
\end{tabular}
\end{center}

(\textit{*})

with $k = 0$ initially.

An informal flow diagram for the procedure is given in fig. 2c. This flow diagram translates easily into the following program $H$ that computes $h$:

\begin{enumerate}
\item $T(1, m+1)$
\item $\vdots$
\item $T(n+1, m+n+1)$
\item $F[1, 2, \ldots, n \rightarrow t+3]$
\item $I_1(n \rightarrow t+1, p)$
\item $G[m+1, \ldots, m+n, t+2, t+3 \rightarrow t+3]$
\item $S(t+2)$
\item $I_1(1, t, q)$
\item $T(t+3, 1)$
\end{enumerate}

Hence $h$ is computable. $\square$

We now proceed to use theorems 3.1 and 4.4 to compile a collection of computable functions. The collection is potentially infinite, so our choice is influenced by (i) the needs of subsequent development of our theory, and (ii) the desire to give credence to the thesis that all functions that we would regard as computable in the informal sense are indeed URM-computable. For reasons which will become apparent later we shall include some functions such as $x + y$ and $x + 1$ for which we have already written programs.

We shall use repeatedly the fact that, by theorem 3.2, in a definition by recursion such as (4.1), the computable functions $f$ and $g$ need not be functions of all of the named variables for the function $h$ to be computable.
4.5. **Theorem**

The following functions are computable. (Proofs are given as the functions are listed.)

(a) \( x + y \)  
   **Proof.** Example 4.3(a) gives a definition by recursion from the computable functions \( x \) and \( z + 1 \).

(b) \( xy \)  
   **Proof.** \( x \cdot 0 = 0 \),  
   \[ x \cdot (y + 1) = xy + x, \]
   is a definition by recursion from the computable functions \( 0(x) \) and \( z + x \).

(c) \( x^y \)  
   **Proof.** \( x^0 = 1 \),  
   \[ x^{y+1} = x^y \cdot x; \] by recursion and (b).

(d) \( x - 1 \)  
   **Proof.** \( 0 - 1 = 0 \),  
   \[ (x + 1) - 1 = x; \] by recursion.

(e) \( x \div y = \begin{cases} x-y & \text{if } x \geq y, \\ 0 & \text{otherwise.} \end{cases} \) (cut-off subtraction)  
   **Proof.** \( x - 0 = x \),  
   \[ x - (y + 1) = (x - y) - 1; \] by recursion and (d).

(f) \( \text{sg}(x) = \begin{cases} 0 & \text{if } x = 0, \\ 1 & \text{if } x \neq 0. \end{cases} \) (cf. exercises 1-3.3(1a))  
   **Proof.** \( \text{sg}(0) = 0 \),  
   \( \text{sg}(x + 1) = 1; \) by recursion.

(g) \( \overline{\text{sg}}(x) = \begin{cases} 1 & \text{if } x = 0, \\ 0 & \text{if } x \neq 0. \end{cases} \) (cf. example 1-4.2(b))  
   **Proof.** \( \overline{\text{sg}}(x) = 1 - \text{sg}(x); \) by substitution, (e) and (f).

(h) \( x - y \)  
   **Proof.** \( x - y = (x - y) + (y - x); \) by substitution, (a) and (e).

(i) \( x! \)  
   **Proof.** Example 4.3(b) gives a definition by recursion from computable functions.

(j) \( \text{min}(x, y) = \text{minimum of } x \text{ and } y \).  
   **Proof.** \( \text{min}(x, y) = x - (x - y); \) by substitution.

(k) \( \text{max}(x, y) = \text{maximum of } x \text{ and } y \).  
   **Proof.** \( \text{max}(x, y) = x + (y - x); \) by substitution.

(l) \( \text{rm}(x, y) = \text{remainder when } y \text{ is divided by } x \) (to obtain a total function, we adopt the convention \( \text{rm}(0, y) = y \)).  
   **Proof.** We have  
   \[ \text{rm}(x, y + 1) = \begin{cases} \text{rm}(x, y) + 1 & \text{if } \text{rm}(x, y) + 1 \neq x, \\ 0 & \text{if } \text{rm}(x, y) + 1 = x. \end{cases} \]
   This gives the following definition by recursion:  
   \( \text{rm}(x, 0) = 0 \),  
   \[ \text{rm}(x, y + 1) - (\text{rm}(x, y) + 1) \text{sg}(x - (\text{rm}(x, y) + 1)) \]

The second equation can be written  
\( \text{rm}(x, y + 1) - g(x, \text{rm}(x, y)) \)  
where \( g(x, z) = (z + 1) \text{sg}(x - (z + 1)) \); and \( g \) is computable by several applications of substitution.  
Hence \( \text{rm}(x, y) \) is computable.

(m) \( \text{qt}(x, y) = \text{quotient when } y \text{ is divided by } x \) (to obtain a total function, we define \( \text{qt}(0, y) = 0 \)).  
   **Proof.** Since  
   \[ \text{qt}(x, y + 1) = \begin{cases} \text{qt}(x, y) + 1 & \text{if } \text{rm}(x, y) + 1 = x, \\ \text{qt}(x, y) & \text{if } \text{rm}(x, y) + 1 \neq x, \end{cases} \]
   we have the following definition by recursion from computable functions:  
   \[ \text{qt}(x, 0) = 0, \]
   \[ \text{qt}(x, y + 1) = \text{qt}(x, y) + \text{sg}(x - (\text{rm}(x, y) + 1)); \]

(n) \( \text{div}(x, y) = \begin{cases} 1 & \text{if } x \mid y \text{ (x divides } y), \\ 0 & \text{if } x \nmid y. \end{cases} \) (We adopt the convention that \( 0 \div 0 \) is undefined for \( y \neq 0 \).) Hence \( x \mid y \) is decidable (recall definition 1-4.1).  
   **Proof.** \( \text{div}(x, y) = \overline{\text{sg}}(\text{rm}(x, y)) \), computable by substitution.

4.6. **Corollary (Definition by cases)**

Suppose that \( f_1(x), \ldots, f_n(x) \) are total computable functions, and \( M_1(x), \ldots, M_n(x) \) are decidable predicates, such that for every \( x \) exactly one of \( M_1(x), \ldots, M_n(x) \) holds. Then the function \( g(x) \) given by  
\[ g(x) = \begin{cases} f_1(x) & \text{if } M_1(x) \text{ holds}, \\ f_2(x) & \text{if } M_2(x) \text{ holds}, \\ \vdots & \text{for } i < n \text{ where } \text{sg}(x) \neq 0, \\ f_n(x) & \text{if } M_n(x) \text{ holds}. \end{cases} \]

is computable.

**Proof.** \( g(x) = c_{M_1}(x) f_1(x) + \cdots + c_{M_n}(x) f_n(x) \), computable by substitution using addition and multiplication.

4.7. **Corollary (Algebra of decidability)**

Suppose that \( M(x) \) and \( Q(x) \) are decidable predicates; then the following are also decidable.

(a) \( \neg M(x) \)
(b) ‘$M(x)$ and $O(x)$’
(c) ‘$M(x)$ or $O(x)$’

Proof. The characteristic functions of these predicates are as follows:
(a) ‘not $M(x)$’: $1 - c_M(x)$,
(b) ‘$M(x)$ and $O(x)$’: $c_M(x) c_O(x)$,
(c) ‘$M(x)$ or $O(x)$’: $\max(c_M(x), c_O(x))$ (where we take ‘or’ in the inclusive sense).

Each of the functions on the right is computable provided $c_M$ and $c_O$ are, by substitution in functions from theorem 4.5. □

Recursion can be used to establish the computability of functions obtained by other function building techniques, which we now describe. First, we introduce some notation.

Suppose that $f(x, z)$ is any function; the bounded sum $\sum_{z \leq y} f(x, z)$ and the bounded product $\prod_{z \leq y} f(x, z)$ are the functions of $x, y$ given by the following recursion equations.

\[
\begin{align*}
\sum_{z \leq 0} f(x, z) &= 0, \\
\sum_{z \leq y+1} f(x, z) &= \sum_{z \leq y} f(x, z) + f(x, y), \\
\prod_{z \leq 0} f(x, z) &= 1, \\
\prod_{z \leq y+1} f(x, z) &= \left( \prod_{z \leq y} f(x, z) \right) \cdot f(x, y).
\end{align*}
\]

4.10. Theorem

Suppose that $f(x, z)$ is a total computable function; then so is the function $\mu z < y (f(x, z) = 0)$.

Proof. The equations 4.8 and 4.9 are definitions by recursion from computable functions. □

It is easily seen that if the bound on $z$ in a bounded sum or product is given by any computable function, the result is still computable, as follows.

4.11. Corollary

Suppose that $f(x, z)$ and $k(x, w)$ are total computable functions; then so are the functions $\sum_{z < k(x, w)} f(x, z)$ and $\prod_{z < k(x, w)} f(x, z)$ (both functions of $x, w$).

Proof. By substitution of $k(x, w)$ for $y$ in the bounded sum $\sum_{z < y} f(x, z)$ and the bounded product $\prod_{z < y} f(x, z)$. □

We now describe another useful function building technique which yields computable functions. We write

\[
\mu z < y (f(x, z))
\]

for ‘the least $z$ less than $y$ such that $f(x, z) = 0$’. In order that this expression be totally defined, we give it the value $y$ when no such $z$ exists. Then, for example, given a function $f(x, z)$ we can define a new function $g$ by

\[
g(x, y) = \mu z < y (f(x, z) = 0) = \begin{cases} \text{the least } z < y \text{ such that } f(x, z) = 0, & \text{if such a } z \text{ exists;} \\ y, & \text{if there is no such } z. \end{cases}
\]

The operator $\mu z < y$ is called a bounded minimalisation operator or bounded $\mu$-operator.

4.12. Theorem

Suppose that $f(x, y)$ is a total computable function; then so is the function $\mu z < y f(x, z) = 0)$.

Proof. Consider the function

\[
h(x, z) = \prod_{z \leq x} \sg(f(x, u)),
\]

which is computable by corollary 4.11. For a given $x, y$, suppose that $z_0 = \mu z < y f(x, z) = 0)$. It is easy to see that

\[
\text{if } z < z_0, \text{ then } h(x, z) = 1;
\]
\[
\text{if } z_0 = z < y, \text{ then } h(x, z) = 0.
\]

Thus

\[
z_0 = \text{the number of } z \text{ less than } y \text{ such that } h(x, z) = 1,
\]
\[
= \sum_{z < y} k(x, z).
\]

Hence

\[
\mu z < y f(x, z) = 0) = \sum_{y \leq y} \left( \prod_{y \leq y} \sg(f(x, u)) \right),
\]

and is computable by theorem 4.10. □

As with bounded sums and products, the bound in bounded minimalisation can be given by any computable function.
4.13. Corollary

If \( f(x, z) \) and \( k(x, w) \) are total computable functions, then so is the function

\[
\mu z < k(x, w) f(x, z) = 0.
\]

Proof. By substitution of \( k(x, w) \) for \( y \) in the computable function \( \mu z < y f(x, z) = 0 \).

Theorems 4.10 and 4.12 give us the following applications involving decidable predicates.

4.14. Corollary

Suppose that \( R(x, y) \) is a decidable predicate; then

(a) the function \( f(x, y) = \mu z < y R(x, z) \) is computable.

(b) the following predicates are decidable:

(i) \( M_1(x, y) = \forall z < y R(x, z) \),

(ii) \( M_2(x, y) = \exists z < y R(x, z) \).

Proof.

(a) \( f(x, y) = \mu z < y \text{sg}(c_R(x, z)) = 0 \).

(b) \( c_R(x, y) = \prod_{z < y} c_R(x, z) \).

Note. As in 4.11 and 4.13, the bound on \( z \) in this corollary could be any total computable function.

We now use the above techniques to enlarge our collection of particular computable functions and decidable properties.

4.15. Theorem

The following functions are computable:

(a) \( D(x) = \text{the number of divisors of } x \) (convention: \( D(0) = 1 \)),

(b) \( P(x) = \begin{cases} 1 & \text{if } x \text{ is prime,} \\ 0 & \text{if } x \text{ is not prime} \end{cases} \)

(i.e. 'x is prime' is decidable),

(c) \( p_x = \text{the } x\text{th prime number (as a convention we set } p_0 = 0, \text{ then } p_1 = 2, p_2 = 3, \text{ etc.}) \)

(d) \( \nu(x, y) = \begin{cases} \text{the exponent of } p_x \text{ in the prime factorisation of } x, & \text{for } x, y > 0, \\ 0 & \text{if } x = 0 \text{ or } y = 0. \end{cases} \)

Proof.

(a) \( D(x) = \sum_{y \in \mathbb{N}} \text{div}(y, x) \) (where \( \text{div} \) is as in theorem 4.5(b)).

(b) \( P(x) = \begin{cases} 1 & \text{if } D(x) = 2 \text{ (i.e. } x > 1 \text{ and the only divisors of } x \text{ are } 1 \text{ and } x), \\ 0 & \text{otherwise} \end{cases} \)

Note. The function \( \text{sg}(D(x) - 2) \) is \( \text{div}(y, x) \) is computable since the predicate 'relatively prime' is decidable.

Alternative ways of coding pairs and sequences are indicated in exercises 4.16 (2, 5) below.
in such a way that if \( f \) is computable then so is \( g \). Two problems can arise.
First, for some \( x \) there may not be any \( y \) such that \( f(x, y) = 0 \). Second, assuming that \( f \) is computable, consider the following natural algorithm for computing \( g(x) \): Compute \( f(x, 0), f(x, 1), \ldots \) until \( y \) is found such that \( f(x, y) = 0 \). This procedure may not terminate if \( f \) is not total, even if such a \( y \) exists; for instance, if \( f(x, 0) \) is undefined but \( f(x, 1) = 0 \).

Thus we are led to the following definition of the minimisation operator \( \mu \), which yields computable functions from computable functions.

5.1. Definition
For any function \( f(x, y) \)

\[
\mu y f(x, y) = \begin{cases} y : f(x, y) = 0 & \text{if there is such a } y \\
\text{undefined} & \text{if there is no such } y.
\end{cases}
\]

\( \mu y (\ldots) \) is read 'the least \( y \) such that \( \ldots \). This operator is sometimes called simply the \( \mu \)-operator.

The next theorem shows that \( \mu \) is closed under minimisation.

5.2. Theorem
Suppose that \( f(x, y) \) is computable; then so is the function \( g(x) = \mu y f(x, y) \).

Proof. Suppose that \( x = (x_1, \ldots, x_n) \) and that \( F \) is a program in standard form that computes the function \( f(x, y) \). Let \( m = \max(x + 1, p(F)) \). We write a program \( G \) that embodies the natural algorithm for \( g \): for \( k = 0, 1, 2, \ldots \), compute \( f(x, k) \) until a value of \( k \) is found such that \( f(x, k) = 0 \); this value of \( k \) is the required output.

The value of \( x \) and the current value of \( k \) will be stored in registers \( R_{m+1}, \ldots, R_{m+n+1} \) before computing \( f(x, k) \); thus the typical configuration will be

<table>
<thead>
<tr>
<th>Storage registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R_1 \ldots R_m )</td>
</tr>
<tr>
<td>( R_{m+1} \ldots R_{m+n} )</td>
</tr>
<tr>
<td>( R_{m+n+1} )</td>
</tr>
<tr>
<td>( R_{m+n+2} )</td>
</tr>
</tbody>
</table>

with \( k = 0 \) initially. Note that \( r_{m+n+2} \) is always 0.
A flow diagram that carries out the above procedure for $g$ is given in fig. 2d. This translates easily into the following program $G$ for $g$:
\[
T(1, \, m + 1) \\
\vdots \\
T(n, \, m + n) \\
I_q \quad F[m + 1, \, m + 2, \ldots, \, m + n + 1 \rightarrow 1] \\
J(1, \, m + n + 2, \, q) \\
S(m + n + 1) \\
J(1, \, 1, \, p) \\
I_q \quad T(m + n + 1, \, 1) \\
\] (The first instruction of the subroutine $F[m + 1, \, m + 2, \ldots, \rightarrow 1]$.) $\square$

Fig. 2d. Minimalisation (theorem 5.2).

5.3. Corollary

Suppose that $R(x, y)$ is a decidable predicate; then the function
\[
g(x) = \mu y \, R(x, y) \\
\begin{cases} 
\text{the least } y \text{ such that } R(x, y) \text{ holds}, & \text{if there is such a } y, \\
\text{undefined} & \text{otherwise}. 
\end{cases}
\]
is computable

Proof. $g(x) = \mu y (S_R(y) \equiv 0)$. $\square$

In view of this corollary, the $\mu$-operator is often called a search operator. Given a decidable predicate $R(x, y)$ the function $g(x)$ searches for a $y$ such that $R(x, y)$ holds, and moreover, finds the least such $y$ if there is one.

The $\mu$-operator may generate a non-total computable function from a total computable function; for instance, putting $f(x, y) = |x - y|^2$, and $g(x) = \mu y (f(x, y) = 0)$, we have that $g$ is the non-total function
\[
g(x) = \begin{cases} 
\sqrt{x} & \text{if } x \text{ is a perfect square}, \\
\text{undefined} & \text{otherwise}. 
\end{cases}
\]

Thus, in a trivial sense, using the $\mu$-operator together with substitution and recursion, we can generate from the basic functions more functions than can be obtained using only substitution and recursion (since these operations always yield total functions from total functions). There are also, however, total functions for which the use of the $\mu$-operator is essential. Example 5.5 below gives one such function; we present another example in chapter 5. Thus we see that, in a strong sense, minimalisation, unlike bounded minimalisation, cannot be defined in terms of substitution and recursion. It turns out, nevertheless, that most commonly occurring computable total functions can be built up from the basic functions using substitution and recursion only: such functions are called primitive recursive, and are discussed further in chapter 3 § 3. In practice, of course, we might establish the computability of these functions by what amounts to a non-essential use of minimalisation, if this makes the task easier.

5.4. Exercises

1. Suppose that $f(x)$ is a total injective computable function; prove that $f^{-1}$ is computable.

2. Suppose that $p(x)$ is a polynomial with integer coefficients; show that the function
5.5. Example (The Ackermann function)

The function \(\psi(x, y)\) given by the following equations is computable:

\[
\begin{align*}
\psi(0, y) &= y + 1, \\
\psi(x + 1, 0) &= \psi(x, 1), \\
\psi(x + 1, y + 1) &= \psi(x, \psi(x + 1, y)).
\end{align*}
\]

This definition involves a kind of double recursion that is stronger than the primitive recursion discussed in §3. To see, nevertheless, that these equations do unambiguously define a function, notice that any value \(\psi(x, y)\) \((x > 0)\) is defined in terms of 'earlier' values \(\psi(x, y_1)\) with \(x_1 < x\) or \(x_1 = x\) and \(y_1 < y\). In fact, \(\psi(x, y)\) can be obtained by using only a finite number of such earlier values: this is easily established by induction on \(x\) and \(y\). Hence \(\psi\) is computable in the informal sense. For instance, it is easy to calculate that \(\psi(1, 1) = 3\) and \(\psi(2, 1) = 5\).

To show rigorously that \(\psi\) is computable is quite difficult. We sketch a proof using the idea of a suitable set of triples \(S\). The essential property of a suitable set \(S\) (defined below) is that if \((x, y, z) \in S\), then

\[
\begin{align*}
(i) \quad z &= \psi(x, y), \\
(ii) \quad \psi(x, y) &= \psi(x, y_1, \psi(x_1, y_1)) \text{ for all } x_1 < x \text{ with } \psi(x_1, y_1) \text{ defined.}
\end{align*}
\]

These three conditions correspond to the three clauses in the definition of \(\psi\): for instance, \((i)\) corresponds to the statement: if \(z = \psi(0, y)\), then \(z = y + 1\); \((ii)\) corresponds to the statement: if \(z = \psi(x + 1, y)\), then there is \(u\) such that \(u = \psi(x + 1, y)\) and \(z = \psi(x, u)\).

The definition of a suitable set \(S\) ensures that (5.6) is satisfied. Moreover, for any particular pair of numbers \((m, n)\) there is a suitable set \(S\) such that \((m, n, \psi(m, n)) \in S\); for example, let \(S\) be the set of triples \((x, y, \psi(x, y))\) that are used in the calculation of \(\psi(m, n)\).

Now a triple \((x, y, z)\) can be coded by the single positive number \(u = 2^x 3^y 5^z\); a finite set of positive numbers \(\{u_1, \ldots, u_k\}\) can be coded by the single number \(p_1 p_2 \ldots p_k\). Hence a finite set of triples can be coded by a single number \(u\) say. Let \(S_u\) denote the set of triples coded by the number \(u\). Then we have

\[
(x, y, z) \in S_u \iff p_{u_1} u_{u_2} \ldots u_{u_k} \text{ divides } u.
\]

so '\((x, y, z) \in S_u\)' is a decidable predicate of \(x, y, z, u\); and if it holds, then \(x, y, z < v\). Hence, using the techniques and functions of earlier sections we can show that the following predicate is decidable:

\[
R(x, y, u) = \psi(x, y) < u \iff R(x, y) \text{ is the code number of a suitable set of triples and } \exists z < u ((x, y, z) \in S_u).\]

Thus the function

\[
f(x, y) = \mu u R(x, y, u)
\]

is a computable function that searches for the code of a suitable set containing \((x, y, z)\) for some \(z\). Hence

\[
\psi(x, y) = \mu u (x, y, z) \in S_u \iff S_u
\]

which shows that \(\psi\) is computable.

A more sophisticated proof that \(\psi\) is computable will be given in chapter 10 as an application of more advanced theoretical results.

We do not prove here that \(\psi\) cannot be shown to be computable using substitution and recursion alone. This matter is further discussed in §3 of the next chapter.
3 Other approaches to computability: Church's thesis

Over the past fifty years there have been many proposals for a precise mathematical characterisation of the intuitive idea of effective computability. The URM approach is one of the more recent of these. In this chapter we pause in our investigation of URM-computability itself to consider two related questions.

1. How do the many different approaches to the characterisation of computability compare with each other, and in particular with URM-computability?
2. How well do these approaches (particularly the URM approach) characterise the informal idea of effective computability?

The first question will be discussed in §§1-6; the second will be taken up in §7. The reader interested only in the technical development of the theory in this book may omit §§3-6; none of the development in later chapters depends on these sections.

1. Other approaches to computability

The following are some of the alternative characterisations that have been proposed:

(a) Gödel-Herbrand-Kleene (1936). General recursive functions defined by means of an equation calculus. (Kleene [1952], Mendelson [1964].)
(b) Church (1936). A-definable functions. (Church [1936] or [1941].)
(c) Gödel-Kleene (1936). μ-recursion functions and partial recursive functions (§2 of this chapter.)
(d) Turing (1936). Functions computable by finite machines known as Turing machines. (Turing [1936]; §4 of this chapter.)
(e) Post (1943). Functions defined from canonical deduction systems. (Post [1943], Minsky [1967]; §5 of this chapter.)

(f) Markov (1951). Functions given by certain algorithms over a finite alphabet. (Markov [1954], Mendelson [1964]; §5 of this chapter.)
(g) Shepherdson-Sturgis (1963). URM-computable functions. (Shepherdson & Sturgis [1963].)

There is great diversity among these various approaches; each has its own rationale for being considered a plausible characterisation of computability. The remarkable result of investigation by many researchers is the following:

1.1. The Fundamental result

Each of the above proposals for a characterisation of the notion of effective computability gives rise to the same class of functions, the class that we have denoted \( \mathcal{R} \).

Thus we have the simplest possible answer to the first question posed above. Before discussing the second question, we shall examine briefly the approaches of Gödel-Kleene, Turing, Post and Markov, mentioned above, and we will sketch some of the proofs of the equivalence of these with the URM approach. The reader interested to discover full details of these and other approaches, and proofs of all the equivalences in the Fundamental result, may consult the references indicated.

2. Partial recursive functions (Gödel-Kleene)

2.1. Definition

The class \( \mathcal{R} \) of partial recursive functions is the smallest class of partial functions that contains the basic functions \( 0, x + 1, \text{U}_7 \) (lemma 2.1.1) and is closed under the operations of substitution, recursion and minimalisation. (Equivalently, \( \mathcal{R} \) is the class of partial functions that can be built up from the basic functions by a finite number of operations of substitution, recursion or minimalisation.)

Note that in the definition of the class \( \mathcal{R} \), no restriction is placed on the use of the \( \mu \)-operator, so that \( \mathcal{R} \) contains non-total functions. Gödel and Kleene originally confined their attention to total functions; the class of functions first considered was the class \( \mathcal{R}_0 \) of \( \mu \)-recursive functions, defined like \( \mathcal{R} \) above, except that applications of the \( \mu \)-operator are allowed only if a total function results. Thus \( \mathcal{R}_0 \) is a class of total functions, and clearly \( \mathcal{R}_0 \subseteq \mathcal{R} \). In fact, \( \mathcal{R}_0 \) contains all of the total
functions that are in $\mathcal{R}$, although this is not immediately obvious; see corollary 2.3 below for a proof. Hence $\mathcal{R}$ is a natural extension of $\mathcal{R}_0$ to a class of partial functions.

The term recursive function is used nowadays to describe $\mu$-recursive functions, so a recursive function is always total—it is a totally defined partial recursive function. The term general recursive function is sometimes used to describe $\mu$-recursive functions, although historically, this was the name Kleene gave to the total functions given by his equation calculus approach ($\alpha$) in §1. It was Kleene who proved the equivalence of general recursive functions (given by the equation calculus) and $\mu$-recursive functions.

We now outline a proof of

2.2. **Theorem**

\[ R = \mathcal{C}. \]

**Proof.** From the main results of chapter 2 (lemma 1.1, theorems 3.1, 4.4, 5.2) it follows that $R \subseteq \mathcal{C}$.

For the converse, suppose that $f(x)$ is a URM-computable function, computed by a program $P = I_1, \ldots, I_k$. By a step in a computation $P(x)$ we mean the implementation of one instruction. Consider the following functions connected with computations under $P$:

\[
c(x, r) = \begin{cases} 
\text{contents of } R_1 \text{ after } r \text{ steps in the computation } P(x), & \text{if } P(x) \text{ has not already stopped;} \\
\text{the final contents of } R_1 \text{ if } P(x) \text{ has stopped after fewer than } r \text{ steps.} & 
\end{cases}
\]

\[
j(x, r) = \begin{cases} 
\text{number of the next instruction, when } t \text{ steps of the computation } P(x) \text{ have been performed,} & \\
\text{if } P(x) \text{ has not stopped after } r \text{ steps or fewer;} & \\
0 & \text{if } P(x) \text{ has stopped after } t \text{ steps or fewer.}
\end{cases}
\]

Clearly $c$ and $j$ are total functions.

If $f(x)$ is defined, then $P(x)$ converges after exactly $t_0$ steps, where

\[ t_0 = \mu t(j(x, t) = 0), \]

and then

\[ f(x) = c(x, t_0). \]

If, on the other hand, $f(x)$ is not defined, then $P(x)$ diverges, and so $j(x, t)$ is never zero. Thus $\mu t(j(x, t) = 0)$ is undefined. Hence, in either case, we have

\[ f(x) = c(x, \mu t(j(x, t) = 0)). \]

So, to show that $f$ is partial recursive, it is sufficient to show that $c$ and $j$ are recursive functions. It is clear that these functions are computable in the informal sense—we can simply simulate the computation $P(x)$ for up to $r$ steps. By a detailed analysis of computations $P(x)$ and utilising many of the functions obtained in chapter 2, it is not difficult, though rather tedious, to show that $c$ and $j$ are recursive; in fact, they can be obtained from the basic functions without the use of minimalisation (so they are primitive recursive—see §3 of this chapter). (A detailed proof of rather more than this will be given in chapter 5—theorem 1.2 and Appendix.) Hence $f$ is partial recursive. $\square$

2.3. **Corollary**

Every total function in $\mathcal{R}$ belongs to $\mathcal{R}_0$.

**Proof.** Suppose that $f(x)$ is a total function in $\mathcal{R}$; then $f$ is URM-computable by a program $P$. Let $c$ and $j$ be the functions defined in the proof of theorem 2.2; as noted there, these can be obtained without any use of minimalisation, so in particular they are in $\mathcal{R}_0$. Further, since $f$ is total, $P(x)$ converges for every $x$, so the function $\mu t(j(x, t) = 0)$ is total and belongs to $\mathcal{R}_0$. Now

\[ f(x) = c(x, \mu t(j(x, t) = 0)), \]

so $f$ also is in $\mathcal{R}_0$. $\square$

A predicate $M(x)$ whose characteristic function $c_M$ is recursive is called a recursive predicate. In view of theorem 2.2, a recursive predicate is the same as a decidable predicate.

3. **A digression: the primitive recursive functions**

This is a natural point to mention an important subclass of $\mathcal{R}$, the class of primitive recursive functions, although they do not form part of the main line of thought in this chapter. These functions were referred to in chapter 2 §5.

3.1. **Definition**

(a) The class $\mathcal{P}R$ of primitive recursive functions is the smallest class of functions that contains the basic functions $0, x + 1, U$, and is closed under the operations of substitution and recursion.
(b) A primitive recursive predicate is one whose characteristic function is primitive recursive.

All of the particular computable functions obtained in §§ 1, 3, 4 of chapter 2 are primitive recursive, since minimalisation was not used there. We have already noted that the functions $c$ and $f$ used in the proof of theorem 2.2 are primitive recursive. Further, from theorems 2, 4.-10 and 4.-12 we see that $PR$ is closed under bounded sums and products, and under bounded minimalisation. Thus the class of primitive recursive functions is quite extensive.

There are nevertheless recursive functions (or, equivalently, total computable functions) that are not primitive recursive. Indeed, the Ackermann function $\psi$ of example 2-5.5 was given as an instance of such a function. A detailed proof that the Ackermann function is not primitive recursive is rather lengthy, and we refer the reader to Péter [1967, chapter 9] or Mendelson [1964, p. 250, exercise 11]. Essentially one shows that $\psi$ grows faster than any given primitive recursive function. (To see how fast $\psi$ grows try to calculate a few simple values.)

In chapter 5 we will be able to give an example of a total computable (i.e., recursive) function that we shall prove is not primitive recursive.

Our conclusion is that although the primitive recursive functions form a natural and very extensive class, they do not include all computable functions and thus fall short as a possible characterisation of the informal notion of computability.

4. Turing-computability

The definition of computability proposed by A.M. Turing [1936] is based on an analysis of a human agent's implementation of an algorithm, using pen and paper. Turing viewed this as a succession of very simple acts of the following kinds:

(a) writing or erasing a single symbol.

(b) transferring attention from one part of the paper to another.

At each stage the algorithm specifies the action to be performed next. This depends only on (i) the symbol on the part of the paper currently being scrutinised by the agent, and (ii) the current state (of mind) of the agent. For the purposes of implementing the algorithm this is assumed to be determined entirely by the agent and the history of the operation so far. It may incorporate a partial record of what has happened to date, but it will not reflect the mood or intelligence of the agent, or the state of his indigestion. Moreover, there are only finitely many distinguishable

states in which the agent can be, because he is finite. The state of the agent may, of course, change as a result of the action taken at this stage.

Turing devised finite machines that carry out algorithms conceived in this way. There is a different machine for each algorithm. We shall briefly describe these machines, which have become known as Turing machines.

4.1. Turing machines.

A Turing machine $M$ is a finite device, which performs operations on a paper tape. This tape is infinite in both directions, and is divided into single squares along its length. (The tape represents the paper used by a human agent implementing an algorithm; each square represents a portion of the paper capable of being viewed in a given instant. In any particular terminating computation under $M$ only a finite part of the tape will be used, although we may not know in advance how much will be needed. The tape is nevertheless infinite, corresponding to the human situation where we envisage an unlimited supply of clean paper.)

At any given time each square of the tape is either blank or contains a single symbol from a fixed finite list of symbols $s_1, s_2, \ldots, s_n$, the alphabet of $M$. We will let $B$ denote a blank, and count it as the symbol $s_1$ belonging to $M$'s alphabet.

$M$ has a reading head which at any given time scans or reads a single square of the tape. We can visualise this as shown in fig. 3a.

$M$ is capable of three kinds of simple operation on the tape, namely:
(a) erase the symbol in the square being scanned and replace it by another symbol from the alphabet of \( M \);
(b) move the reading head one square to the right of that being scanned (or, equivalently, move the tape one square to the right);
(c) move the reading head one square to the left of that being scanned (or, equivalently, move the tape one square to the left).

At any given time \( M \) is in one of a fixed finite number of states, represented by symbols \( q_1, \ldots, q_n \). During operation the state of \( M \) can change. We may envisage the symbol for the current state as being displayed in a window on the exterior of \( M \) (as in fig. 3a), and think of this as a partial guide to what has happened to date and what will happen in the future.

The action that \( M \) takes at any instant depends on the current state of \( M \) and on the symbol currently being scanned. This dependence is described in \( M \)'s specification which consists of a finite set \( Q \) of quadruples, each of which takes one of the following forms:

\[
q_i \alpha s_j q_k \quad (1 \leq i, j \leq m)
\]

\[
q_i \alpha R q_k \quad (0 \leq j, k \leq n)
\]

\[
q_i \alpha L q_k
\]

A quadruple \( q_i \alpha s_j q_k \) in \( Q \) specifies the action to be taken by \( M \) when it is in the state \( q_i \) and scanning the symbol \( s_j \), as follows:

1. Operate on the tape thus:
   (a) if \( \alpha = s_i \), erase \( s_i \) in the square being scanned;
   (b) if \( \alpha = R \), move the reading head one square to the right;
   (c) if \( \alpha = L \), move the reading head one square to the left;
2. Change into state \( q_k \).

The specification \( Q \) is such that for every pair \( q_i \alpha \) there is at most one quadruple of the form \( q_i \alpha s_j \beta \); otherwise there could be ambiguity about what \( M \) does next.

To begin a computation, \( M \) must be provided with a tape and positioned so that a specified square is being scanned; further, \( M \) must be set in some prescribed initial state. Then, if \( M \) is in the state \( q_i \) and scans the symbol \( s_j \), it acts as described above provided that there is a quadruple of the form \( q_i \alpha s_j q_k \) in \( Q \). This kind of action is then repeated for the new state and symbol scanned, and so on. \( M \) continues in this way for as long as possible. The operation of \( M \) terminates only when it is in a state \( q_t \) scanning a symbol \( s_i \) such that there is no quadruple of the form \( q_t \alpha s_i \beta \) in

\( Q \); i.e. there is no quadruple in \( Q \) that specifies what to do next. (It is possible that this never happens.)

4.2. Example

Let \( M \) be a Turing machine whose alphabet consists of the symbols 0, 1, (and a blank of course) and whose possible states are \( q_1 \) and \( q_2 \). The specification of \( M \) is:

\[
q_1 0 R q_2
q_1 1 q_2
q_2 0 R q_2
q_2 1 R q_2
\]

Suppose that \( M \) is provided with the tape

\[
\ldots \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ \ldots
\]

scanning the square marked 1, and initially in state \( q_1 \). It is easy to see that \( M \)'s action is to work from left to right along the tape, replacing alternate 1s by the symbol 0; \( M \) stops when it scans the first blank square since there is no quadruple that specifies what it should do. The resulting tape is

\[
\ldots \ 0 \ 1 \ 0 \ 1 \ 0 \ 1 \ 0 \ 1 \ \ldots
\]

with the square marked 1 being scanned, and \( M \) is in state \( q_1 \).

On the other hand, if \( M \) is provided with a tape such that every square contains the symbol 0 or 1, then the operation of \( M \) never stops.

It is clear from this example that a Turing machine \( M \) is a device for effecting an algorithm that operates on tapes. Complete details of the algorithm are contained in the specification \( Q \) of \( M \). Thus, for the mathematician, a Turing machine is defined to be the set of quadruples that specify it. It is not usual to build physical Turing machines, except for illustrative purposes.

4.3. Turing-computable functions

In order to regard a Turing machine \( M \) as computing a numerical function, we must use some convention for representing numbers on a tape. One way is as follows: suppose, for convenience of exposition, that the symbol \( s_1 \) of \( M \)'s alphabet is 1. We use 1 as a 'tally symbol', and then
represent a number \( x \) on the tape as follows (ignore the marker \( \downarrow \) for the moment):

\[
\begin{array}{cccccccc}
\ldots & 1 & 1 & 1 & \ldots & 1 & 1 & \ldots \\
\end{array}
\]

\[\leftrightarrow x + 1 \text{ squares} \]

We use \( x + 1 \) tallys to represent \( x \), so as to distinguish 0 from a blank tape.

The partial function \( f(x) \) computed by \( M \) is defined as follows. Consider the computation by \( M \) on the above tape, starting in state \( q_i \), and initially scanning the square marked \( \downarrow \). Then

\[
f(x) = \begin{cases} 
\text{the total number of occurrences of the symbol } 1 \\
\text{on the final tape, if this computation eventually stops;} \\
\text{undefined otherwise.}
\end{cases}
\]

Similarly, the \( n \)-ary partial function \( f(x_1, \ldots, x_n) \) computed by \( M \) is defined by counting the number of 1s on the final tape when \( M \) is started in state \( q_i \) and scanning the square marked \( \downarrow \) on the following tape:

\[
\begin{array}{cccccccc}
\ldots & 1 & 1 & \ldots & 1 & 1 & \ldots & 1 & 1 & \ldots \\
\end{array}
\]

\[\leftrightarrow x_1 + 1 \text{ squares} \leftrightarrow x_2 + 1 \text{ squares} \leftrightarrow x_n + 1 \text{ squares} \]

4.6. **Exercises**

1. What unary function is Turing-computed by the machine in example 4.22?

2. Devise Turing machines that will Turing-compute the functions

   (a) \( x - 1 \)
   (b) \( 2x \).

It is not our purpose here to develop the theory of Turing machines and Turing-computable functions; the interested reader should consult the books by Davis [1958], or Minsky [1967] listed in the bibliography.

The fundamental result linking Turing-computability with partial recursive functions and URM-computability is the following:

4.7. **Theorem**

\( \mathcal{R} = \mathcal{F} \mathcal{C} = \mathcal{C} \).

**Proof.** There are various ways of establishing this result, which we indicate in barest outline.

A direct proof that \( \mathcal{F} \mathcal{C} \subseteq \mathcal{R} \) is somewhat similar to the proof that \( \mathcal{C} \subseteq \mathcal{R} \) (Theorem 2.2). The tape configurations and states of a Turing machine during a computation can be coded by natural numbers, and the operation of the machine is then represented by recursive functions of these numbers.

For the converse inclusion, \( \mathcal{R} \subseteq \mathcal{F} \mathcal{C} \), one can show directly that \( \mathcal{F} \mathcal{C} \) contains the basic functions and is closed under substitution, recursion, and minimisation. This is done in detail in Davis [1958]. Alternatively, one can show that \( \mathcal{C} \subseteq \mathcal{F} \mathcal{C} \) by showing that URM's are equivalent in power to a succession of simpler machines, ending with Turing machines. This is the proof given in their original paper by Shepherdson & Sturgis [1963]. \( \Box \)

5. **Symbol manipulation systems of Post and Markov**

E. L. Post and A. A. Markov formulated their ideas of effectiveness in terms of strings of symbols. They recognised that objects (including numbers) to which effective processes apply can always be represented as strings of symbols; in fact, in contexts such as symbolic logic, abstract algebra and the analysis of languages the objects actually
are strings of symbols. Both Post and Markov, from different points of view, considered that effective operations on strings of symbols are those that are built up from very simple manipulations of the strings themselves.

Post's central idea was that of a canonical system, which we describe below. Such systems do not compute functions; they generate sets of strings. This is because Post aimed to characterize formal logical systems, i.e., systems that generate theorems from axioms by the mechanical application of rules of logic. Thus a notion of effectiveness emerges from Post's work, initially in the guise of effectively (or mechanically) generated sets. We shall see how a notion of a Post-computable function can be derived from this.

In paragraph 5.17 below we explore the way in which Markov's approach is related to that of Post.

We must now define some notation to aid our discussion. Let \( \Sigma = \{a_1, \ldots, a_k\} \) be a finite set of symbols, called an alphabet. A string from \( \Sigma \) is any sequence \( a_1 \ldots a_n \) of symbols from \( \Sigma \). Strings are sometimes called words, by analogy with ordinary language. For any alphabet \( \Sigma \), we write \( \Sigma^* \) to denote the set of all strings from \( \Sigma \). Included in \( \Sigma^* \) is the empty string, denoted \( \lambda \), that has no symbols. If \( \sigma = b_1b_2 \ldots b_n \) and \( \tau = c_1 \ldots c_m \) are strings then \( \sigma \tau \) denotes the string \( b_1 \ldots b_n c_1 \ldots c_m \). The empty string \( \lambda \) has the property that for any string \( \sigma \), \( \sigma \lambda = \sigma = \lambda \sigma \).

5.1. Post-systems

In elementary algebra a common operation is to replace the string \((x - y)(x + y)\) whenever it occurs by the string \((x^2 - y^2)\). This string manipulation may be denoted by writing

\[
S_1(x - y)(x + y)S_2 \rightarrow S_1(x^2 - y^2)S_2
\]

where \( S_1 \) and \( S_2 \) are arbitrary strings.

A more general manipulation of a string, yet still regarded by Post as elementary, takes the form

\[
g_0S_1g_1S_2 \ldots g_{m-1}S_mg_m \rightarrow h_0S_1h_1S_2h_2 \ldots S_mh_m
\]

where

(i) \( g_0, \ldots, g_m, h_0, \ldots, h_m \) are fixed strings (and may be null),
(ii) the subscripts \( i_1, \ldots, i_n \) are all from \( 1, 2, \ldots, m \), and need not be distinct.

Post called an operation of the form (5.2) a production; it may be applied to any string \( \sigma \) that can be analyzed as

\[
\sigma = \sigma_1 \sigma_2 \ldots \sigma_m \quad (\sigma_1, \ldots, \sigma_m \text{ are strings}),
\]

to produce the string \( h_0 \sigma_1 h_1 \sigma_2 h_2 \ldots \sigma_m h_m \).

5.3. Example

Let \( \Sigma = \{a, b\} \); consider the production

\[
(\pi) \quad aS_1bS_2 \rightarrow S_2aS_2a.
\]

Then the effect of \( (\pi) \) on some strings is given in the table

<table>
<thead>
<tr>
<th>( \sigma )</th>
<th>Strings produced by ( (\pi) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>aba</td>
<td>aaaa</td>
</tr>
<tr>
<td>abba</td>
<td>aaaa and baaba</td>
</tr>
<tr>
<td>ha</td>
<td>(\pi) does not apply</td>
</tr>
</tbody>
</table>

(The entries in the second line correspond to the two possible analyses of \( abba \): \( a \cdot b \cdot b \cdot a \) and \( a \cdot A \cdot b \cdot b \cdot a \).

5.4. Exercise

Examine the ways in which the production

\[
S_1bS_2aS_2b \rightarrow S_2abS_1
\]

applies to the string \( babaabaab \).

Productions form the main ingredient of Post's canonical systems:

5.5. Definition

A Post-(canonical) system \( \mathcal{G} \) consists of

(a) a finite alphabet \( \Sigma \),
(b) a finite subset \( A \) of \( \Sigma^* \), the axioms of \( \mathcal{G} \),
(c) a finite set \( Q \) of productions of the form (5.2), whose fixed strings are in \( \Sigma^* \).

We say that \( \mathcal{G} \) is a Post-system over \( \Sigma \).

We write \( \sigma \overset{\mathcal{G}}{\rightarrow} \tau \) if the string \( \tau \) can be obtained from the string \( \sigma \) by a finite succession of applications of productions in \( \mathcal{G} \); then we write \( \overset{\mathcal{G}}{\Rightarrow} \tau \) if there is an axiom \( \sigma \in A \) such that \( \sigma \overset{\mathcal{G}}{\rightarrow} \tau \). In this case we say that \( \tau \) is generated by the Post-system; the set of all strings in \( \Sigma^* \) generated by \( \mathcal{G} \) is denoted \( T_\mathcal{G} \), i.e.,

\[
T_\mathcal{G} = \{ \sigma \in \Sigma^* : \overset{\mathcal{G}}{\Rightarrow} \sigma \}.
\]
The set $T_\mathcal{G}$ is also called the set of *theorems* of $\mathcal{G}$, reflecting the original motivation of Post.

5.6. Example
Let $\mathcal{G}$ be the Post-system with alphabet $\Sigma = \{a, b\}$, axioms $A, a, b$ and productions $S \rightarrow aSa$ and $S \rightarrow bSb$. Then $T_\mathcal{G}$ is the set of *palindromes*—the strings reading the same in either direction, such as $aba, bbbab, abba$.

Sometimes, in order to generate a particular set of strings in $\Sigma^*$, it is necessary to use auxiliary symbols in the generation process. This leads to the following definition:

5.7. Definition
Let $\Sigma$ be an alphabet and let $X \subseteq \Sigma^*$. Then $X$ is *Post-generable* if there is an alphabet $\Sigma_1 \supseteq \Sigma$ and a Post-system $\mathcal{G}$ over $\Sigma_1$ such that $X$ is the set of strings in $\Sigma_1^*$ that are generated by $\mathcal{G}$, i.e., $X = T_\mathcal{G} \cap \Sigma^*$.

Post proved a remarkable theorem showing that really only very simple productions are needed to generate Post-generable sets. A set of productions $\mathcal{Q}$ (and any system in which they occur) is said to be *normal* if all the productions have the form $gS \rightarrow Sh$.

Post proved

5.8. Theorem (Post's normal form theorem)
Any Post-generable set can be generated by a normal system.

For an excellent proof consult Minsky [1967].

Post-systems having only productions of the kind

$$S_1gS_2 \rightarrow S_1hS_2$$

give models of grammars and languages. They reflect the way in which complex sentences of a language are built up from certain basic units according to the rules of grammar. Restrictions on the nature of $g$ and $h$ provide the context-sensitive and context-free languages of Chomsky, which provide useful models of languages used in computer programming. We cannot pursue this interesting topic here: the reader may consult the books of Arbib [1969] and Manna [1974] for further information.

5.9. Post-systems and other approaches to computability
As we have seen, Post-systems give a characterisation of the notion of an effectively generated set. We may compare this with the corresponding notion that emerges from the other approaches to computability. For URM-computability (or Turing-computability, etc.) effectively generated sets of numbers are called *recursively enumerable* (r.e.); these are the sets that are the range of some URM-computable function. (We shall study r.e. sets in chapter 7.)

To compare sets of *strings* with sets of numbers, we choose an (intuitively) effective coding function $\sigma: \Sigma^* \rightarrow \mathbb{N}$ under which the string $\sigma \in \Sigma^*$ is coded by the number $\sigma$. A convenient method for an alphabet $\Sigma = \{a_1, \ldots, a_k\}$ is by the $k$-adic coding where $\sigma: \Sigma^* \rightarrow \mathbb{N}$ is defined by $A = 0$; $i = 2, \ldots, k$. It is easily seen that $\sigma$ is actually a bijection, so if the inverse of $\sigma$ is denoted by $\sigma^{-1}: \mathbb{N} \rightarrow \Sigma^*$ we also have a representation of each number $n$ by a string $\sigma(n)$.

Suppose now that $X$ is a set of strings: let $\bar{X} = \{\sigma: \sigma \in X\}$, the set of numbers coding $X$. We have the equivalence result:

5.10. Theorem
$X$ is Post-generable if and only if $\bar{X}$ is r.e.

Proof. We sketch one proof of this result. Let $X \subseteq \Sigma^*$ and suppose first that $\bar{X}$ is r.e. Let $\bar{X} = \text{Ran}(f)$, where $f$ is URM-computable. Using earlier equivalences we can design a Turing machine $M$ whose symbols include the alphabet $\Sigma$, so that when in state $q_1$ and given initial tape

$$
\begin{array}{c}
\downarrow \\
1 \quad 1 \\
\ldots \\
M + 1 \\
\end{array}
$$

$M$ halts if and only if $m \in \text{Dom}(f)$, and does so in the following configuration

$$
\begin{array}{c}
\downarrow \\
(q_m) \\
\end{array}
$$

i.e. the symbols on the non-blank part of the tape indicated constitute the string $f(m)$ from $\Sigma$, and $M$ is in a special halting state $q_m$ scanning the square marked $\downarrow$. Now devise a Post-system $\mathcal{G}$ to simulate the behaviour of $M$ on its tape; the alphabet of $\mathcal{G}$ will include $\Sigma$ and the symbols and
states of \( M; \mathcal{G} \) will generate strings of the form
\[ s_1, s_2, \ldots, s_k, s_{k+1}, \ldots s_m, \]
to represent any situation

that occurs during the computation by \( M \) from an initial tape of the form (\( * \)). To get things going, \( \mathcal{G} \) will generate all strings of the form
\[ q_0 \text{ IIII} \ldots \text{III} \]
which represent such initial tapes. If we include in \( \mathcal{G} \) the production \( q_0 S \rightarrow S \), then the strings from \( \Sigma^* \) generated by \( \mathcal{G} \) will be the set
\[ \{ \langle m, n \rangle; m \in \text{Dom}(f) \} = \{ \langle n \rangle; n \in \text{Ran}(f) \} = \{ \langle n \rangle; n \in X \} = X. \]
Thus \( X = T_\mathcal{G} \cap \Sigma^* \), so \( X \) is Post-generable.

Conversely, if \( X \) is Post-generable by a Post-system \( \mathcal{G} \), show that the relation
\[ \langle n \rangle \text{ is generated by } \mathcal{G} \text{ using at most } m \text{ productions} \]
is decidable; from the theory of r.e. sets (chapter 7) it follows easily that \( X \) is r.e. \( \square \)

5.11. Post-computability

We now explain two ways to derive a concept of computable function from Post-systems. In both cases, the concept is defined first for functions on \( \Sigma^* \), and then extended to \( \mathbb{N} \) by coding or representation.

Suppose that \( f: \Sigma^* \rightarrow \Sigma^* \) is a partial function. Select a symbol \( \cdot \) not in \( \Sigma \) and consider the set of strings
\[ G(f) = \{ \langle \sigma \cdot f(\sigma) \rangle; \sigma \in \text{Dom}(f) \} \]
from the alphabet \( \Sigma \cup \{ \cdot \} \). The set \( G(f) \) contains all information about \( f \), and we define:

5.12. Definition
\( f: \Sigma^* \rightarrow \Sigma^* \) is Post-computable if \( G(f) \) is Post-generable.

5.13. Example
Let \( \Sigma = \{ 1 \} \) and consider the function \( f: \Sigma^* \rightarrow \Sigma^* \) given by
\[ f(\lambda) = \lambda, \]
\[ f(1 \ldots 1) = 111 \ldots 111. \]
\[ \leftarrow n \rightarrow \quad \leftrightarrow n^2 \rightarrow \]

The set \( G(f) \) is generated by the following Post-system:

- **Alphabet** \( \{ 1, \cdot \} \)
- **Axiom** \( \langle A \rangle \cdot f(A) \)
- **Production** \( S_1 \cdot S_2 \rightarrow S_1 \cdot S_2 S_1 S_1 \)

The single production of this system applies to a string of the form
\[ 11 \ldots 111 \ldots 111 \]
\[ \leftarrow n \rightarrow \quad \leftrightarrow n^2 \rightarrow \]
to produce the string
\[ 11 \ldots 111 \ldots 1111 \ldots 111 \ldots 111 \]
\[ \leftarrow n + 1 \rightarrow \quad \leftrightarrow n^2 \rightarrow \rightarrow n \rightarrow \]

Hence \( f \) is Post-computable.

Suppose that \( G(f) \) is generated by a Post-system \( \mathcal{G} \). To see that \( f \) is computable in the informal sense, consider the following algorithm for finding \( f(\sigma) \) (where \( \sigma \in \Sigma^* \)).

'Generate the strings \( T_\mathcal{G} \) in some systematic fashion; examine these as they appear, looking for a string of the form \( \sigma \cdot \tau \) with \( \tau \in \Sigma^* \). Such a string will eventually be produced if, and only if, \( \sigma \in \text{Dom}(f) \), and then \( \tau = f(\sigma) \).'

The definition (5.12) extends in an obvious way to partial functions \( \langle \Sigma^* \rangle' \rightarrow \Sigma^* \). Post-computability on \( \mathbb{N} \) is then defined using any effective representation \( \mathbb{N} \rightarrow \Sigma^* \) in the natural way:

5.14. Definition
Let \( g: \mathbb{N} \rightarrow \mathbb{N} \) be a partial function, and let \( \tilde{g}: \langle \Sigma^* \rangle' \rightarrow \Sigma^* \) be the function defined by
\[ \tilde{g}(m_1, m_2, \ldots, m_n) = g(m_1, \ldots, m_n) \quad (m_1, \ldots, m_n \in \mathbb{N}). \]
Then \( g \) is Post-computable if \( \tilde{g} \) is Post-computable.

If we let \( \mathcal{P} \) denote the class of Post-computable functions of natural numbers, we have the equivalence:

5.15. Theorem
\[ \mathcal{P} = \mathcal{C} = \mathcal{R}. \] (We omit a proof. When the reader has studied chapters 6 and 7 he should be able to see that this follows from theorem 5.10 and the results of chapters 6 and 7 linking r.e. sets with URM-computable functions.)
6.2. Example

\( D = \Sigma^* \), where \( \Sigma = \{a, b\} \). The class \( \mathcal{R}^D \) of partial recursive functions on \( \Sigma^* \) is the smallest class of partial functions such that

(a) the basic functions

(i) \( f(\lambda) = \lambda \)

(ii) \( f(\sigma \cdot \lambda) = \sigma \alpha \)

(iii) \( f(\sigma \cdot \beta) = \sigma \beta \)

(iv) the projection functions \( \pi_i^\Sigma(\sigma_1, \ldots, \sigma_n) = \sigma_i \)

are in \( \mathcal{R}^D \).

(b) \( \mathcal{R}^D \) is closed under substitution.

(c) \( \mathcal{R}^D \) is closed under primitive recursive definitions of the following form:

\[
\begin{align*}
  h(\sigma, \lambda) & = f(\sigma) \\
  h(\sigma, \alpha \cdot \lambda) & = g_1(\sigma, \alpha), h(\sigma, \lambda) \\
  h(\sigma, \gamma \cdot \beta) & = g_2(\sigma, \gamma), h(\sigma, \beta)
\end{align*}
\]

where \( f, g_1, g_2 \in \mathcal{R}^D \).

(d) \( \mathcal{R}^D \) is closed under minimalisation: if \( f(\sigma, \tau) \) is in \( \mathcal{R}^D \), so is the function \( h \) given by

\[
h(\sigma) = \mu \tau (f(\sigma, \tau) = \lambda)
\]

where \( \mu \tau \) means the first \( \tau \) in the natural ordering \( \Lambda, a, b, aa, ab, ba, bb, aab, aba, \ldots \).

For each of these, and other approaches to computability on a domain \( D \) that utilise the intrinsic structure of \( D \), we find as expected that they are equivalent to the approach that transfers the notion of computability from \( \mathbb{N} \) by using coding. And, vice versa, any natural notion of computability on a domain \( D \) induces an alternative (but equivalent) notion of computability on \( \mathbb{N} \) via coding, as with Post-computability in § 5.

6.3. Exercises

1. Prove that URM-computability on \( \mathbb{Z} \) as outlined in example 6.1 is equivalent to URM-computability via coding (example 1-5.1).

2. Prove that the class \( \mathcal{R}^D \) of partial recursive functions on \( \Sigma^* \), as defined in example 6.2, is identical to the Post-computable functions on \( \Sigma^* \).

3. Suggest natural definitions of computability on the domains (a) \( 3 \times 3 \) matrices, (b) \( \mathbb{Q} \) (rational numbers).

4. Give a natural definition of Turing-computability on \( \Sigma^* \), where \( \Sigma \) is any finite alphabet.

7. Church’s thesis

We now turn our attention to the second question of the introduction to this chapter: how well is the informal and intuitive idea of effectively computable function captured by the various formal characterisations?

In the light of their investigations, Church, Turing and Markov each put forward the claim that the class of functions he had defined coincides with the informally defined class of effectively computable functions. In view of the Fundamental result (1.1), these claims are all mathematically equivalent. The name Church’s thesis (sometimes the Church–Turing thesis) is now used to describe any of these other claims. Thus, in terms of the URM approach, we can state:

Church’s thesis

The intuitively and informally defined class of effectively computable partial functions coincides exactly with the class \( \mathcal{C} \) of URM-computable functions.

Note immediately that this thesis is not a theorem which is susceptible to mathematical proof; it has the status of a claim or belief which must be substantiated by evidence. The evidence for Church’s thesis, which we summarise below, is impressive.

1. The Fundamental result: many independent proposals for a precise formulation of the intuitive idea have led to the same class of functions, which we have called \( \mathcal{C} \).

2. A vast collection of effectively computable functions has been shown explicitly to belong to \( \mathcal{C} \); the particular functions of chapter 2 constitute the beginning of such a collection, which can be enlarged ad infinitum by the techniques of that chapter, and other more sophisticated methods.

3. The implementation of a program \( P \) on the URM to compute a function is clearly an example of an algorithm; thus, directly from the definition of the class \( \mathcal{C} \), we see that all functions in \( \mathcal{C} \) are computable in the formal sense. Similarly with all the other equivalent classes, the very definitions are such as to demonstrate that the functions involved are effectively computable.

4. No one has ever found a function that would be accepted as computable in the informal sense, that does not belong to \( \mathcal{C} \).

On the basis of this evidence, and that of their own experience, most mathematicians are led to accept Church’s thesis. For our part, we
propose to accept and use Church's thesis throughout the rest of this book, in a way that we now explain.

Suppose that we have an informally described algorithm for computing the values of a function \( f \). Such an algorithm may be described in English, or by means of diagrams, or in semi-formal mathematical terms, or by any other means that communicate unambiguously how to effectively calculate the values of \( f \), where defined, in a finite amount of time. In such a situation we may wish to prove that \( f \) is URM-computable. There are, broadly, two methods open to us.

Method 1. Write a program that URM-computes \( f \) (and prove that it does so), or prove by indirect means that such a program exists. This could be done, for instance, by the methods of chapter 2, or by showing that \( f \) belongs to one of the many classes shown by the Fundamental result to be equivalent to \( \varepsilon \).

Such a full and formal proof that \( f \) is URM-computable may be a long and rather technical process. Essentially it would involve translation of the informally described algorithm into a program or into the language of one of the other formal characterisations. Probably there would be various flow diagrams as intermediate translations.

Method 2. Give an informal (though rigorous) proof that the given informal algorithm is indeed an algorithm that serves to compute \( f \). Then appeal to Church's thesis and conclude immediately that \( f \) is URM-computable.

We propose to accept method 2 as a valid method of proof, which we call proof by Church's thesis.

7.1. Examples

1. Let \( P(x) \) be a URM program; define a function \( f \) by

\[
f(x, y, t) = \begin{cases} 1 & \text{if } P(x) \text{ halts in } t \text{ or fewer steps} \\ 0 & \text{otherwise}. \end{cases}
\]

An informal algorithm for computing \( f \) is as follows.

'Given \( (x, y, t) \), simulate the computation \( P(x) \) (on a piece of paper, for example, as in example 1-2.1), carrying out \( t \) steps of \( P(x) \) unless this computation stops after fewer than \( t \) steps. If \( P(x) \) stops after \( t \) or fewer steps, with \( y \) finally in \( R_x \), then \( f(x, y, t) = 1 \). Otherwise (i.e. if \( P(x) \) stops in \( t \) or fewer steps with

some number other than \( y \) in \( R_x \), or if \( P(x) \) has not stopped after \( t \) steps) we have \( f(x, y, t) = 0 \).'

Simulation of \( P(x) \) for at most \( t \) steps is clearly a mechanical procedure, which can be completed in a finite amount of time. Thus, \( f \) is effectively computable. Hence, by Church's thesis, \( f \) is URM-computable.

2. Suppose that \( f \) and \( g \) are unary effectively computable functions. Define a function \( h \) by

\[
h(x) = \begin{cases} 1 & \text{if } x \in \text{Dom}(f) \text{ or } x \in \text{Dom}(g), \\ \text{undefined} & \text{otherwise}. \end{cases}
\]

An algorithm for \( h \) can be described in terms of given algorithms for the effectively computable functions \( f \) and \( g \) as follows:

'Given \( x \), start the algorithms for computing \( f(x) \) and \( g(x) \) simultaneously. (Envisage two agents or machines working simultaneously, or one agent who does one step of each algorithm alternately.) If and when one of these computations terminates, then stop altogether, and set \( h(x) = 1 \). Otherwise, continue indefinitely.'

This algorithm gives \( h(x) = 1 \) for any \( x \) such that either \( f(x) \) or \( g(x) \) is defined; and it goes on for ever if neither is defined. Thus we have an algorithm for computing \( h \), so by Church's thesis \( h \) is URM-computable.

3. Let \( f(n) \) be the \( n \)-th digit in the decimal expansion of \( \pi = 3.14159 \ldots \) (so we have \( f(0) = 3, f(1) = 1, f(2) = 4, \ldots \)). We can obtain an informal algorithm for computing \( f(n) \) as follows. Consider Hutton's series for \( \pi \)

\[
\pi = \sum_{k=0}^{\infty} \frac{1}{4k+1} \left( \frac{1}{15} \right)^{2k} + \frac{1}{4k+3} \left( \frac{1}{6} \right)^{2k} + \frac{1}{4k+2} \left( \frac{1}{3} \right)^{2k} + \cdots
\]

Let \( s_k = \sum_{n=0}^{k} h_n \); by the elementary theory of infinite series

\[
s_k < \pi < s_k + 1/10^k.
\]

Now \( s_k \) is rational, so the decimal expansion of \( s_k \) can be effectively calculated to any desired number of places using long division. Thus the following is an effective method for calculating \( f(n) \) (given a number \( n \)):
Find the first $N = n + 1$ such that the decimal expansion

$$s_N = a_0 \cdot a_1 a_2 \ldots a_n a_{n+1} \ldots$$

does not have all of $a_{n+1}, \ldots, a_N$ equal to 9. (Such an $N$ exists, for otherwise the decimal expansion of $\pi$ would end in recurring 9, making $\pi$ rational.) Then put $f(n) = a_n$.

To see that this gives the required value, suppose that $a_n \neq 9$ with $n < m \leq N$. Then by the above

$$s_N < \pi \leq s_N + 1/10^N$$

$$\leq s_N + 1/10^m.$$

Hence $a_0 \cdot a_1 \ldots a_n \ldots < \pi < a_0 \cdot a_1 \ldots a_n \ldots (a_{n+1}) \ldots$ so the $n$th decimal place of $\pi$ is indeed $a_n$.

Hence by Church's thesis, $f$ is computable.

The student should try to provide complete formal proofs (method 1) that the functions in these examples are URM-computable (assuming, for example 2, that $f$ and $g$ are URM-computable). For all of them it is a lengthy and tedious task.

Note that in using Church's thesis we are not proposing to abandon all thought of proof, as if Church's thesis is a magic wand which we can wave instead. A proof by Church's thesis will always involve proof that is careful, and sometimes complicated, although informal. Moreover, anyone using Church's thesis in the way we propose should be able to provide a formal proof if challenged. (As if to anticipate such a challenge, we provide in the appendix to chapter 5 an alternative formal proof of one fundamental theorem in that chapter (theorem 5.1.2) on which almost all later development depends. This then serves to substantiate further Church's thesis: incidentally, it is a simple formal corollary that the functions in the first two examples above are URM-computable also.)

Church's thesis not only keeps proofs shorter, but also prevents the main idea of a proof or construction from being obscured by a mass of technical details. It remains, however, an expression of faith or confidence. The validity of faith depends on the evidence that can be mustered. In the case of Church's thesis, there is the mathematical evidence already outlined. For the practised student there is the additional evidence of his own experience in translating informal algorithms into formal counterparts. For the beginner, our use of Church's thesis in subsequent chapters may call on his willingness to place confidence in the ability of others until self-confidence is developed.

7.2. Exercises

1. Suppose that $f(x)$ and $g(x)$ are effectively computable functions. Prove, using Church's thesis, that the function $h$ given by

$$h(x) = \begin{cases} x & \text{if } x \in \text{Dom}(f) \cap \text{Dom}(g), \\ \text{undefined} & \text{otherwise} \end{cases}$$

is URM-computable.

2. Suppose that $f$ is a total unary computable function. Prove, by Church's thesis, that the following function $h$ is URM-computable

$$h(x) = \begin{cases} 1 & \text{if } x \in \text{Ran}(f), \\ \text{undefined} & \text{otherwise.} \end{cases}$$

3. Give a detailed proof by Church's thesis that the Ackermann function (example 2.5.5) is computable.

4. Prove by Church's thesis that the function $g$ given by

$$g(n) = \text{ith digit in the decimal expansion of } e$$

is computable (where the number $e$ is the basis for natural logarithms).
4
Numbering computable functions

We return now to the study of URM-computable functions. Henceforth the term computable standing alone means URM-computable, and program means URM program.

The key fact established in this chapter is that the set of all programs is effectively denumerable; in other words there is an effective coding of programs by the set of all natural numbers. Among other things, it follows that the class \( \mathcal{C} \) is denumerable, which implies that there are many functions that are not computable. In \( \S 3 \) we discuss Cantor's diagonal method, whereby this is established.

The numbering or coding of programs, and particularly its effectiveness, is absolutely fundamental to the development of the theory of computability. We cannot overemphasize its importance. From it we obtain codes or indices for computable functions, and this means that we are able to pursue the idea of effective operations involving such codes.

In \( \S 4 \) we prove the first of two important theorems involving codes of functions: the so-called \( s-m-n \) theorem of Kleene. (The second theorem is the main result of chapter 5.)

1. Numbering programs

We first explain the terminology that we shall use.

1.1. Definitions
(a) A set \( X \) is denumerable if there is a bijection \( f: X \to \mathbb{N} \). (Note. The term countable is normally used to mean finite or denumerable; thus, for infinite sets, countable means the same as denumerable. The term countably infinite is used by some authors instead of denumerable.)
(b) An enumeration of a set \( X \) is a surjection \( g: \mathbb{N} \to X \); this is often represented by writing
\[ X = \{x_0, x_1, x_2, \ldots \} \]

where \( x_n = g(n) \). This is an enumeration without repetitions if \( g \) is injective.
(c) Let \( X \) be a set of finite objects (for example a set of integers, or a set of instructions, or a set of programs); then \( X \) is effectively denumerable if there is a bijection \( f: X \to \mathbb{N} \) such that both \( f \) and \( f^{-1} \) are effectively computable functions.

(Note. We mean here the informal notion of effectively computable. This is compelled upon us since, in general, there is no available formal notion of computability of functions from \( X \) to \( \mathbb{N} \). In cases where some formal notion does apply, we take this to be the meaning, as for example in theorem 1.2(a).)

Clearly, a set is denumerable if and only if it can be enumerated without repetitions.

For the main result of this section we need the following (recall that \( \mathbb{N}^+ \) denotes the set of all positive natural numbers):

1.2. Theorem
The following sets are effectively denumerable.
(a) \( \mathbb{N} \times \mathbb{N} \).
(b) \( \mathbb{N}^+ \times \mathbb{N}^+ \times \mathbb{N}^+ \).
(c) \( \bigcup_{k>0} \mathbb{N}^k \), the set of all finite sequences of natural numbers.

Proof
(a) A bijection \( \pi: \mathbb{N} \times \mathbb{N} \to \mathbb{N} \) is defined by
\[ \pi(m, n) = 2^m(2n + 1) - 1. \]
It is clear from the definition that \( \pi \) is in fact a computable function; to see that the inverse is effectively computable observe that \( \pi^{-1} \) is given by
\[ \pi^{-1}(x) = (\pi_1(x), \pi_2(x)), \]
where \( \pi_1, \pi_2 \) are the computable functions defined by \( \pi_1(x) = (x + 1), \pi_2(x) = (x + 1)/2^{\pi_1(x)} - 1. \) (Cf. exercise 2.4.16.(2)).
(b) An explicit bijection \( \xi: \mathbb{N}^+ \times \mathbb{N}^+ \times \mathbb{N}^+ \to \mathbb{N} \) is given, using the function \( \pi \) of (a), by
\[ \xi(m, n, q) = \pi(\pi(m - 1, n - 1), q - 1). \]
Then we have
\[ \xi^{-1}(x) = (\pi_1(\pi_1(x)) + 1, \pi_2(\pi_1(x)) + 1, \pi_3(x) + 1). \]

To say that we should use a notion of computability based on some coding begs the whole question, since a coding is an effective (in the informal sense) function.
Since the functions \( \pi, \pi_1, \pi_2 \) are effectively computable, then so are \( \zeta \) and \( \zeta^{-1} \).

(c) A bijection \( \tau : \cup_{k \geq 0} \mathbb{N}^k \rightarrow \mathbb{N} \) is defined by
\[
\tau(a_1, \ldots, a_k) = 2^{a_1} + 2^{a_2} \cdot a_1 - 1 + 2^{a_3} \cdot a_1 \cdot a_2 - 1 + \cdots + 2^{a_k} \cdot a_1 \cdot a_2 \cdots a_{k-1} - 1.
\]

Clearly \( \tau \) is an effectively computable function. To see that \( \tau \) is a bijection, and to calculate \( \tau^{-1}(x) \), we use the fact that each natural number has a unique expression as a binary decimal. Thus, given \( x \), we can effectively find unique numbers \( k \geq 1 \) and \( 0 \leq b_1 < b_2 < \cdots < b_k \) such that
\[
x + 1 = 2^{b_1} + 2^{b_2} \cdot b_1 - 1 + 2^{b_3} \cdot b_1 \cdot b_2 - 1 + \cdots + 2^{b_k} \cdot b_1 \cdot b_2 \cdots b_{k-1} - 1
\]
from which we obtain
\[
\tau^{-1}(x) = (a_1, \ldots, a_k),
\]
where \( a_i = b_i \) and \( a_{i+1} = b_i + 1 - b_i - 1 \) (1 \( \leq i \leq k \). (Cf. exercise 2-4.16(5), where functions closely connected with the calculation of \( \tau^{-1} \) are to be proved computable.) \( \square \)

Let us now denote the set of all URM instructions by \( \mathcal{I} \), and the set of all programs by \( \mathcal{F} \). A program consists of a finite list of instructions, so we next consider the set \( \mathcal{F} \).

1.3. Theorem
\( \mathcal{F} \) is effectively denumerable.

Proof. We define an explicit bijection \( \beta : \mathcal{F} \rightarrow \mathbb{N} \) that maps the four kinds of instruction onto natural numbers of the forms \( 4u, 4u+1, 4u+2, 4u+3 \) respectively; we use the functions \( \pi \) and \( \zeta \) defined in the proof of theorem 1.2.
\[
\beta(Z(n)) = 4(n+1),
\]
\[
\beta(S(n)) = 4(n+1) + 1,
\]
\[
\beta(T(m, n)) = 4 \pi (m-1, n-1) + 2,
\]
\[
\beta(J(z, m, n, q)) = 4 \zeta (m, n, q) + 3.
\]
This explicit definition shows that \( \beta \) is effectively computable. To find \( \beta^{-1}(x) \), first find \( u, r \) such that \( x = 4u + r \) with \( 0 \leq r < 4 \). The value of \( r \) indicates which kind of instruction \( \beta^{-1}(x) \) is, and from \( u \) we can effectively find the particular instruction of that kind. Specifically:
- if \( r = 0 \), then \( \beta^{-1}(x) = Z(x+1) \);
- if \( r = 1 \), then \( \beta^{-1}(x) = S(x+1) \);
- if \( r = 2 \), then \( \beta^{-1}(x) = T(\pi_1(u) + 1, \pi_2(u)+1) \);
- if \( r = 3 \), then \( \beta^{-1}(x) = J(m, n, q) \), where \( (m, n, q) = \zeta^{-1}(u) \).

Hence \( \beta^{-1} \) is also effectively computable. \( \square \)

Now we can prove:

1.4. Theorem
\( \mathcal{P} \) is effectively denumerable.

Proof. Define an explicit bijection \( \gamma : \mathcal{P} \rightarrow \mathbb{N} \) as follows, using the bijections \( \tau \) and \( \beta \) of theorems 1.2 and 1.3: if \( \Pi = I_1, I_2, \ldots, I_l \), then
\[
\gamma(\Pi) = \tau(\beta(I_1), \ldots, \beta(I_l)).
\]
Since \( \tau \) and \( \beta \) are bijections, so is \( \gamma \); the fact that \( \tau \) and \( \beta \) and their inverses are effectively computable ensures that \( \gamma \) and \( \gamma^{-1} \) are also effectively computable. \( \square \)

The bijection \( \gamma \) will play an important role in subsequent development. For a program \( \Pi \), the number \( \gamma(\Pi) \) is called the code number of \( \Pi \), or the Gödel number of \( \Pi \), or just the number of \( \Pi \). We define
\[
P_n = \text{the program with (code) number } n
\]
and say that \( P_n \) is the \( n \)th program. By construction of \( \gamma \), if \( m \neq n \), then \( P_m \) differs from \( P_n \) although these programs may compute the same functions.

It is of the utmost importance for later results that the functions \( \gamma \) and \( \gamma^{-1} \) are effectively computable, i.e.
(a) Given a particular program \( \Pi \), we can effectively find the code number \( \gamma(\Pi) \);
(b) given a number \( n \), we can effectively find the program \( P_n = \gamma^{-1}(n) \).

In order to emphasize this we give two simple illustrations.

1.5. Examples
(a) Let \( \Pi \) be the program \( T(1, 3), S(4), Z(6) \). We will calculate \( \gamma(\Pi) \).
\[
\beta(T(1, 3)) = 4 \pi (0, 2) + 2 - 4(2 
\times 2 + 1) - 1 + 2 - 18,
\]
\[
\beta(S(4)) = 4 \times 3 + 1 = 13,
\]
\[
\beta(Z(6)) = 4 \times 5 = 20.
\]

\footnote{The term Gödel number is used after K. Gödel, who first exploited the idea of coding non-numerical objects by numbers in his famous paper [Gödel 1931].}
Hence \( \gamma(P) = 2^{18} + 2^{32} + 2^{35} - 1 \)
\[ = 9007203549970431. \]

(b) Let \( n = 4127 \); we will find \( P_{4127} \).
\[ 4127 = 2^5 + 2^3 + 2^2 + 2^1 + 2^0 - 1 , \] hence \( P_{4127} \) is a program with two instructions
\[ I_1, I_2 \]
where
\[ \beta(I_1) = 5 = 4 \times 1 + 1 , \]
\[ \beta(I_2) = 12 = 25 - 1 - 6 = 6 \times 1 + 1 = 6 \times 1 + 2 , \]
Hence from the definition of \( \beta, I_1 = S(2) \) and \( I_2 = T(2, 1) \), so \( P_{4127} \) is
\[ S(2) , \]
\[ T(2, 1) . \]

There are, of course, many other possible effective bijections from \( \mathcal{P} \) to \( \mathbb{N} \); our choice in defining the details of \( \gamma \) was somewhat arbitrary. What is vital, we again emphasise, is that \( \gamma \) and \( \gamma^{-1} \) are effectively computable. The particular details of \( \gamma \) are not so important. For subsequent theory, any other bijection \( \gamma \) would suffice, provided that \( \gamma \) and its inverse are effectively computable. However, we have to fix on one particular numbering of programs, and we have chosen that given by \( \gamma \).

For the rest of this book, \( \gamma \) remains fixed, so that for each particular number \( n \), the meaning of \( P_n \) does not change. Thus, for instance, \( P_{4127} \) always means the program \( S(2), T(2, 1) \).

1.6. **Exercise**

Find

(a) \( \beta((3, 4, 2)) \),
(b) \( \beta^{-1}(503) \),
(c) the code number of the following program:
\[ T(3, 4), S(3), Z(1) , \]
(d) \( P_{100} \).

2. **Numbering computable functions**

Using our fixed numbering of programs, we can now number computable functions and their domains and ranges. We introduce some important notation which is basic to the rest of the book.

2.1. **Definition**

For each \( a \in \mathbb{N} \), and \( n \geq 1 \):

(a) \( \phi_a^{(n)} = \text{the n-ary function computed by } P_a \)
\[ = f_a^{(n)} \text{ in the notation of chapter 1 § 3} . \]
(b) \( W_a^{(n)} = \text{domain of } \phi_a^{(n)} = \{ (x_1, \ldots, x_n) : P_a(x_1, \ldots, x_n) \} , \)
\[ E_a^{(n)} = \text{range of } \phi_a^{(n)} . \]

We shall be mainly concerned with unary computable functions in later chapters, so for convenience we omit the superscript \( (1) \) when it occurs; thus we write \( \phi_a \) for \( \phi_a^{(1)} \), \( W_a \) for \( W_a^{(1)} \), and \( E_a \) for \( E_a^{(1)} \).

2.2. **Example**

Let \( a = 4127 \); from the previous section we know that \( P_{4127} \) is
\[ S(2), T(2, 1) . \]
Hence
\[ \phi_{4127}(x) = 1 \quad \text{ (all x) } \]
and
\[ \phi_{4127}^{(1)}(x_1, \ldots, x_n) = x_1 + 1 \quad \text{ if } n > 1 . \]

Thus
\[ W_{4127} = \mathbb{N} , \quad E_{4127} = \{ 1 \} ; \]
\[ W_{4127}^{(1)} = \mathbb{N} , \quad E_{4127}^{(1)} = \mathbb{N} \text{ if } n > 1 . \]

Suppose that \( f \) is a unary computable function. Then there is a program \( P_a \), say, that computes \( f \), so \( f = \phi_a \), where \( a = \gamma(P) \). We say then that \( a \) is an
index for \( f \). Since there are many different programs that compute a given function, we cannot say that \( a \) is the index for \( f \); in fact, each computable function has infinitely many indices.

We conclude that every unary computable function appears in the enumeration
\[ \phi_0, \phi_1, \phi_2, \ldots . \]
and that this is an enumeration with repetitions.

Similar remarks apply to \( n \)-ary functions and their enumeration.

2.3. **Exercise**

Prove that every computable function has infinitely many indices.

Recall that we denoted the set of all \( n \)-ary computable function by \( \mathcal{C}_n \).

2.4. **Theorem**

\( \mathcal{C}_n \) is denumerable.
Proof. We use the enumeration \( \phi_0^{(n)}, \phi_1^{(n)}, \phi_2^{(n)}, \ldots \) (which has repetitions) to construct one without repetitions.

Let \( f(0) = 0 \).

Let \( f(m) = \min \{ \phi_m^{(n)} \neq \phi_r^{(m)} : \phi_r^{(m)} \neq \phi_{r+1}^{(m)} \} \).

Then

\[ \phi_0^{(n)}, \phi_1^{(n)}, \phi_2^{(n)}, \ldots \]

is an enumeration of \( \mathcal{C}_n \) without repetitions. \( \square \)

Note: We are not claiming that \( f \) as defined in this proof is computable; in fact, nevertheless, we will be able to show later that this is not the case. It is possible, to give a complicated construction of a total computable function \( h \) such that \( \phi_h^{(n)}, \phi_h^{(n+1)}, \ldots \) is an enumeration of \( \mathcal{C}_n \) without repetitions. This was proved by Friedberg [1958].

2.5. Corollary

\( \mathcal{C} \) is denumerable.

Proof. Since \( \mathcal{C} = \bigcup_{n=1}^{\infty} \mathcal{C}_n \), this follows from the fact that a denumerable union of denumerable sets is denumerable.

Explicitly, for each \( n \) let \( f_n \) be the function used in theorem 2.4 to give an enumeration of \( \mathcal{C}_n \) without repetitions. Let \( \pi \) be the bijection \( \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N} \) of theorem 1.2. Define \( \theta : \mathcal{C} \rightarrow \mathbb{N} \) by

\[ \theta(\phi_n^{(m)}) = \pi(m, n-1). \]

Clearly \( \theta \) is a bijection. \( \square \)

The next theorem shows that there are functions that are not computable. The idea of the proof is as important as the result itself.

2.6. Theorem

There is a total unary function that is not computable.

Proof. We shall construct a total function \( f \) that is simultaneously different from every function in the enumeration \( \phi_0, \phi_1, \phi_2, \ldots \) of \( \mathcal{C} \).

Explicitly, define

\[ f(n) = \begin{cases} \phi_n(n) + 1 & \text{if } \phi_n(n) \text{ is defined}, \\ 0 & \text{if } \phi_n(n) \text{ is undefined}. \end{cases} \]

Notice that we have constructed \( f \) so that for each \( n \), \( f \) differs from \( \phi_n \) at \( n \):

- if \( \phi_n(n) \) is defined, then \( f \) differs from \( \phi_n \) in that \( f(n) \neq \phi_n(n) \);
- if \( \phi_n(n) \) is undefined, then \( f \) differs from \( \phi_n \) in that \( f(n) \) is defined.

Since \( f \) differs from every unary computable function \( \phi_n \), \( f \) does not appear in the enumeration of \( \mathcal{C} \) and is thus not itself computable. Clearly \( f \) is total. \( \square \)

3. Discussion: the diagonal method

The method of constructing the function \( f \) in theorem 2.6 is an example of the diagonal method of construction, due to Cantor. Many readers will be familiar with this method as used in proofs of the uncountability of the set of real numbers. The underlying idea is applicable in a wide variety of situations, and is central in the proofs of many results concerning computability and decidability.

To see why the term diagonal is used, consider again the construction of \( f \) in theorem 2.6. Complete details of the functions \( \phi_0, \phi_1, \ldots \) can be represented by the following infinite table:

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \phi_0 )</td>
<td>( \phi_0(0) )</td>
<td>( \phi_0(1) )</td>
<td>( \phi_0(2) )</td>
<td>( \phi_0(3) )</td>
<td>( \ldots )</td>
</tr>
<tr>
<td>( \phi_1 )</td>
<td>( \phi_1(0) )</td>
<td>( \phi_1(1) )</td>
<td>( \phi_1(2) )</td>
<td>( \phi_1(3) )</td>
<td>( \ldots )</td>
</tr>
<tr>
<td>( \phi_2 )</td>
<td>( \phi_2(0) )</td>
<td>( \phi_2(1) )</td>
<td>( \phi_2(2) )</td>
<td>( \phi_2(3) )</td>
<td>( \ldots )</td>
</tr>
<tr>
<td>( \phi_3 )</td>
<td>( \phi_3(0) )</td>
<td>( \phi_3(1) )</td>
<td>( \phi_3(2) )</td>
<td>( \phi_3(3) )</td>
<td>( \ldots )</td>
</tr>
<tr>
<td>( \vdots )</td>
<td>( \vdots )</td>
<td>( \vdots )</td>
<td>( \vdots )</td>
<td>( \vdots )</td>
<td>( \vdots )</td>
</tr>
</tbody>
</table>

We suppose that in this table the word 'undefined' is written whenever \( \phi_n(n) \) is not defined.

The function \( f \) was constructed by taking the diagonal entries on this table (circled)

\[ \phi_0(0), \phi_1(1), \phi_2(2), \ldots \]

and systematically changing them, obtaining

\[ f(0), f(1), f(2), \ldots \]

such that \( f(n) \) differs from \( \phi_n(n) \), for each \( n \). Note that there was considerable freedom in choosing the value of \( f(n) \); we only had to ensure that it differed from \( \phi_n(n) \). Thus

\[ g(n) = \begin{cases} \phi_n(n) + 27^n & \text{if } \phi_n(n) \text{ is defined}, \\ n^2 & \text{if } \phi_n(n) \text{ is undefined}. \end{cases} \]

is another non-computable total function.
We can summarise the diagonal method as we shall be using it, in the following way. Suppose that \( \chi_0, \chi_1, \chi_2, \ldots \) is an enumeration of objects of a certain kind (functions or sets of natural numbers). Then we can construct an object \( \chi \) of the same kind that is different from every \( \chi_n \), using the following motto:

'Make \( \chi \) and \( \chi_n \) differ at \( n \).'

The interpretation of the phrase 'differ at \( n \) depends on the kind of object involved. Functions may differ at \( n \) over whether they are defined, or in their values at \( n \) if defined there; with sets, there is usually freedom to construct \( \chi \) so as to meet specific extra requirements; for instance, that \( \chi \) be computable, or that its domain (or range) should differ from that of each \( \chi_n \).

In the case of sets, the question at \( n \) is whether or not \( n \) is a member. We illustrate the diagonal construction when sets are involved.

3.1. Example

Suppose that \( A_0, A_1, A_2, \ldots \) is an enumeration of subsets of \( \mathbb{N} \).

We can define a new set \( B \), using the diagonal motto, by

\[ B \subseteq A_n \text{ if and only if } n \notin A_n. \]

Clearly, for each \( n, B \neq A_n \).

There are important applications of the diagonal method in the next two chapters.

3.2. Exercises

1. Suppose that \( f(x, y) \) is a total computable function. For each \( m \), let \( g_m \) be the computable function given by

\[ g_m(y) = f(m, y). \]

Construct a total computable function \( h \) such that for each \( m \), \( h \neq g_m \).

2. Let \( f_0, f_1, \ldots \) be an enumeration of partial functions from \( \mathbb{N} \) to \( \mathbb{N} \).

Construct a function \( g \) from \( \mathbb{N} \) to \( \mathbb{N} \) such that \( \text{Dom}(g) \neq \text{Dom}(f_l) \) for each \( l \).

3. Let \( f \) be a partial function from \( \mathbb{N} \) to \( \mathbb{N} \), and let \( m \in \mathbb{N} \). Construct a non-computable function \( g \) such that

\[ g(x) = f(x) \text{ for } x \leq m. \]

4.(a) (Cantor) Show that the set of all functions from \( \mathbb{N} \) to \( \mathbb{N} \) is not denumerable.

(b) Show that the set of all non-computable total functions from \( \mathbb{N} \) to \( \mathbb{N} \) is not denumerable.

4. The \( s \)-m \( n \) theorem

In the final section of this chapter we prove a theorem that has many important uses, especially in conjunction with the main theorem of the next chapter.

Suppose that \( f(x, y) \) is a computable function (not necessarily total). Then for each fixed value \( a \) of \( x, f \) gives rise to a unary computable function \( g_a \), where

\[ g_a(y) = f(a, y). \]

Since \( g_a \) is computable, it has an index \( e \), say, so that

\[ f(a, y) = \phi_e(y). \]

The next theorem shows that such an index \( e \) can be obtained effectively from \( a \). This is a particular case of a more general theorem, known as the \( s \)-m \( n \) theorem, which we prove below. (The reason for this name will be explained after theorem 4.3.) For most purposes in this book, the following suffices.

4.1. Theorem (The \( s \)-m \( n \) theorem, simple form)

Suppose that \( f(x, y) \) is a computable function. There is a total computable function \( k(x) \) such that

\[ f(x, y) = \phi_{k(x)}(y). \]

Proof. For each fixed \( a \), \( k(a) \) will be the code number of a program \( P_a \) which, given initial configuration

\[
\begin{array}{|c|c|c|c|c|c|c|}
\hline
& \text{y} & 0 & 0 & 0 & \ldots \\
\hline
\hline
\end{array}
\]

computes \( f(a, y) \).

Let \( F \) be a program that computes \( f \). Then for \( P_a \), we write down \( F \) prefaced by instructions that transform the configuration \((*)\) to

\[
\begin{array}{|c|c|c|c|c|c|c|}
\hline
& a & y & 0 & 0 & \ldots \\
\hline
\hline
\end{array}
\]
Thus, define $Q_n$ to be the following program:

\[
\begin{align*}
T(1, 2) \\
Z(1) \\
S(1) \\
& \vdots \\
S(1) \\
F
\end{align*}
\]

$a$ times

Now define

\[ k(a) = \text{the code number of the program } Q_a. \]

Since $F$ is fixed, and from the fact that our numbering $\gamma$ of programs is effective, we see that $k$ is an effectively computable function. Hence, by Church's thesis, $k$ is computable. By construction

\[ \phi_{\alpha(a)}(y) = f(a, y) \]

for each $a$. □

The $s$-th theorem is sometimes called the Parametrisation theorem because it shows that an index for a computable function (such as $g_a$ in the discussion above) can be found effectively from a parameter (such as $a$) on which it effectively depends.

Before giving the full $s$-th theorem we give some simple illustrations of the use of theorem 4.1 in effectively indexing certain sequences of computable functions or their domains or ranges.

4.2. Examples

1. Let $f(x, y) = y^x$. By theorem 4.1 there is a total computable $k$ such that $\phi_{k(n)}(y) = y^y$. Hence, for each fixed $n$, $k(n)$ is an index for the function $y^y$.

2. Let $f(x, y) = \begin{cases} y & \text{if } y \text{ is a multiple of } x \\ \text{undefined} & \text{otherwise} \end{cases}$. Then $f$ is computable, so let $k$ be a computable function such that $\phi_{k(n)}(y) = f(x, y)$. Then, for each fixed $n$

\[ \phi_{k(n)}(y) \text{ is defined if and only if } y \text{ is a multiple of } n \]

\[ \text{if } y \text{ is in the range of } \phi_{k(n)}. \]

\[ W_k(n) = \{ n \bar{y} : y \text{ is a multiple of } n \} = E_k(n). \]

So we have an effective indexing of the sequence of sets $(\mathbb{N})$ as (i) the domains of computable functions, (ii) the ranges of computable functions.

---

One obvious way to generalise theorem 4.1 is to replace the single variables $x, y$ by $m$- and $n$-tuples $x$ and $y$ respectively. We can also reflect the fact that the function $k$ defined in the proof of theorem 4.1 depended effectively on a particular program for the original function $f$. Thus, instead of considering a fixed computable function $f(x, y)$ we consider a general computable function $\phi^{(m+n)}_x(x, y)$, and the question of effectively finding, for each $e$ and $x$, a number $z$ such that

\[ \phi^{(m+n)}_x(x, y) = \phi^{(m)}_z(y). \]

4.3. Theorem (The $s$-th theorem)

For each $m, n \geq 1$ there is a total computable $(m+1)$-ary function $s^x_{(e, x)}$ such that

\[ \phi^{(m+1)}_x(x, y) = \phi^{(m)}_{s^x_{(e, x)}}(y). \]

Proof. We generalise the proof of theorem 4.1.

For any $i \geq 1$ let $Q(i, x)$ be the subroutine

\[
\begin{align*}
Z(i) \\
S(i) \\
& \vdots \\
S(i)
\end{align*}
\]

that replaces the current contents of $R_i$ by $x$. Then for fixed $m, n$ define $s^x_{(e, x)}$ to be the code number of the following program:

\[
\begin{align*}
T(n, m+n) \quad & \text{This part of the program transforms any configuration} \\
T(2, m-2) \\
T(1, m+1) \\
Q(1, x_1) \\
Q(2, x_2) \\
& \vdots \\
Q(m, x_m) \\
P
\end{align*}
\]

From this explicit definition, and the effectiveness of $\gamma$ and $\gamma^{-1}$, we get that $s^x_{(e, x)}$ is effectively computable, hence computable, by Church's thesis. □
5
Universal programs

In this chapter we establish the somewhat surprising result that there are
universal programs: i.e., programs that in a sense embody all other
programs. This result is one of the twin pillars that support computability
theory (the other is the s-m-n theorem); both rest on the numbering
of programs given in chapter 4.

Important among the applications of universal programs is the
construction of specific non-computable functions and undecidable
predicates, a topic pursued in chapter 6. We give a foretaste of such
applications in §2 of this chapter; we also use a universal program to
construct a total computable function that is not primitive recursive, as
promised in chapter 3.

The final section of this chapter is devoted to some illustrations of the
use of the s-m-n theorem in conjunction with universal programs to show
that certain operations on the indices of computable functions are
effective (a foretaste of the topic of chapter 10).

1. Universal functions and universal programs

Consider the function \( \psi(x, y) \) defined by

\[
\psi(x, y) = \phi_1(y).
\]

There is an obvious sense in which the single function \( \psi \) embodies all the
unary computable functions \( \phi_0, \phi_1, \phi_2, \ldots \), since for any particular \( m \),
the function \( g \) given by

\[
g(y) = \psi(m, y)
\]

is just the computable function \( d_m \). Thus we describe \( \psi \) as the universal
function for unary computable functions. Generally, we make the
following definition.
1.1. Definition
The universal function for \( n \)-ary computable functions is the \((n + 1)\)-ary function \( \psi^{(n)}_U \) defined by
\[
\psi^{(n)}_U(e, x_1, \ldots, x_n) = \phi^{(n)}_{\sigma}(x_1, \ldots, x_n).
\]
We write \( \psi_U \) for \( \psi^{(n)}_U \).

The question arises, is \( \psi_U \) (or, generally, \( \psi^{(n)}_U \)) a computable function? If so, then any program \( P \) that computes \( \psi_U \) would appear to embody all other programs, and \( P \) would be aptly called a universal program. At first, perhaps, the existence of a universal program seems unlikely. Nevertheless, it is not hard to see that \( \psi_U \) is indeed computable. The point is that a universal program \( P \) does not need to contain all other programs \( P_r \) in itself; \( P \) only needs the ability to decode any number \( e \) and hence mimic \( P_r \).

1.2. Theorem

For each \( n \), the universal function \( \psi^{(n)}_U \) is computable.

Proof. Fix \( n \), and suppose that we are given an index \( e \) and an \( n \)-tuple \( x \).

An informal procedure for computing \( \psi^{(n)}_U(e, x) \) is as follows:

Decode the number \( e \) and write out the program \( P_e \). Now mimic the computation \( P_e(x) \) step by step, at each step writing down the configuration of the registers and the next instruction to be obeyed (as was done in example 1-2.1). If and when this computation stops, then the required value \( \psi^{(n)}_U(e, x) \) is the number currently in \( R_1 \).

We could conclude immediately (using Church's thesis) that \( \psi^{(n)}_U(e, x) \) is computable. Because of the importance of this theorem, however, we prefer to outline the beginnings of a formal proof and then make a rather less sweeping appeal to Church's thesis. (For the sake of completeness of our exposition we shall provide the rest of the formal proof in an appendix to this chapter.)

The plan for a formal proof is to show first how to use a single number \( \sigma \) to code the current situation during a computation; then we shall show that there is a computable function expressing the dependence of \( \sigma \) on (a) the program number \( e \), (b) the input \( x \), (c) the number of steps of the computation that have been completed. We will see that this suffices to prove the theorem.

Let us return then to the computation \( P_e(x) \) considered above. As we have seen in examples, the current situation during a computation is completely specified by (i) the current configuration of the registers...
have
\[ \psi^{(n)}(c, x) = \langle c, x, \mu t \rangle \text{ or } \langle j_n, c, x, t = 0 \rangle \] .

Thus, if \( c_n \) and \( j_n \) are computable, so is \( \psi^{(n)} \) (using substitution and minimalisation) and our proof is complete.

We now use Church's thesis to show that \( \sigma_n \) (and hence \( c_n \) and \( j_n \)) are computable. We have the following informal algorithm for obtaining \( \sigma_n \) effectively from \( \sigma_n \) and \( c \):

'Decode \( \sigma_n \) to find the numbers \( c = c_n(e, x, t) \) and \( j = j_n(e, x, t) \).
If \( j = 0 \), then \( \sigma_n(e, x, t + 1) = \sigma_n(e, x, t) \).
Otherwise, write out the configuration coded by \( c \),
\[
\begin{array}{cccccc}
(c)_1 & (c)_2 & (c)_3 & \ldots & (c)_m & 0 & 0 & \ldots
\end{array}
\]
say, and by decoding \( e \) write out the program \( P_e \). Now find the \( j \)th instruction in \( P_e \) and operate with it on the configuration \((^*)\), producing a new configuration with code \( c' \) say. Find also the number \( j' \) of the new next instruction (with \( j' = 0 \) if the computation has now terminated). Then we have
\[ \sigma_n(e, x, t + 1) = \pi(c', j') \] .

This shows informally that \( \sigma_n \) is computable by recursion in \( n \), since for \( t = 0 \) we have
\[ \sigma_n(e, x, 0) = \pi(2^{n+1}3^m \ldots p_n^m, 1) \]
to start the recursion off. Hence, by Church's thesis, \( \sigma_n \) is computable, and our theorem is now proved. \( \square \)

Note. Since this theorem is so basic to further development, we provide in the appendix a complete formal proof that \( \sigma_n \) (and hence \( \psi^{(n)} \)) is computable. This then provides further evidence for Church's thesis. (Our formal proof also gives us the extra information that \( \sigma_n \) is actually primitive recursive.)

From the proof of this theorem we obtain:

1.3. Corollary
For each \( n \geq 1 \), the following predicates are decidable.
(a) \( S_n(e, x, y, t) \equiv P_e \downarrow \text{ in } t \text{ steps} \) ,
(b) \( H_n(e, x, t) \equiv 'P_e \downarrow \text{ in } t \text{ steps}' \) .

Proof. (a) \( S_n(e, x, y, t) = \mu t = 0 \) and \( (c_n(e, x, t))_1 = y \) .
(b) \( H_n(e, x, t) = \mu t = 0 \) . \( \square \)

The significance of the next corollary is discussed in the first note below.

1.4. Corollary (Kleene's normal form theorem)
There is a total computable function \( U(x) \) and for each \( n \geq 1 \) a decidable predicate \( T_n(e, x, z) \) such that
(a) \( \phi^{(n)}(x) \) is defined if and only if \( \exists z T_n(e, x, z) \) ,
(b) \( \phi^{(n)}(x) = U(\mu z T_n(e, x, z)) \) .

Proof. To discover whether \( \phi^{(n)}(x) \) is defined, and the value if it is, we need to search for a pair of numbers \( y, t \) such that \( S_n(e, x, y, t) \) . We have the \( \mu \)-operator that enables us to search effectively for a single number having a given property. To use this in searching for a pair of numbers, we can think of a single number \( z \) as coding the pair of numbers \( z_1 \) and \( z_2 \) . Then, as \( z \) runs through \( \mathbb{N} \), the pair \( (z_1, z_2) \) runs through \( \mathbb{N} \times \mathbb{N} \) . So we define
\[ T_n(e, x, z) \equiv S_n(e, x, (z_1), (z_2)) \] .

For (a), suppose that \( \phi^{(n)}(x) \) is defined; then there are \( y, t \) such that \( S_n(e, x, y, t) \), so putting \( z = 2^n3^t \) we have \( T_n(e, x, z) \) .

Conversely, if there is \( z \) such that \( T_n(e, x, z) \), then from the definition of \( T_n \), \( P_e \downarrow \text{ in } z \text{ steps} \) . i.e. \( \phi^{(n)}(x) \) is defined.

For (b), it is clear from the definition of \( T_n \) that if \( \phi^{(n)}(x) \) is defined, then for any \( z \) such that \( T_n(e, x, z) \), we have \( \phi^{(n)}(x) = (z_1) \) . So if we put \( U(z) = (z_1) \), then
\[ \phi^{(n)}(x) = U(\mu z T_n(e, x, z)) \] . \( \square \)

Notes
1. From the appendix to this chapter it follows that the functions \( c_n \) and \( j_n \) are primitive recursive. Hence, the predicates \( S_n \), \( T_n \) in corollaries 1.3 and 1.4 are also primitive recursive. Thus, in particular, the Kleene normal form theorem shows that every computable function (or partial recursive function) can be obtained from primitive recursive functions by using at most one application of the \( \mu \)-operator. The theorem gives, moreover, a standard way of doing this.

2. The technique of searching for pairs of numbers by thinking of a single number \( z \) as coding the pair \( (z_1, z_2) \) (as used in the proof of corollary 1.4) is often used in computability theory. We give an exercise needing this technique below (exercise 1.5(1)).

The technique can also be used in searching for sequences \( (x_1, x_2, \ldots, x_n) \) for any \( n > 1 \).
Now suppose that \( g \) is computable; since \( \psi_1 \) is computable, then, by Church's thesis, so is \( f \), which is a contradiction. Hence \( g \) is not computable. \( \square \)

Our second application here fulfills the promise made in chapter 3 § 3.

2.2. Theorem

There is a total computable function that is not primitive recursive.

Proof. We give an informal proof. Recall that the primitive recursive functions are those functions that can be built up from the basic functions by a sequence of applications of the operations of substitution and recursion. Thus each primitive recursive function can be specified by a plan that indicates the basic functions used and the exact sequence of operations performed in its construction. To describe such a plan it is convenient to adopt some notation such as the following:

Sub\((f; g_1, g_2, \ldots, g_m)\) denotes the function obtained by substituting \( g_1, \ldots, g_m \) into \( f \) (assuming that \( f \) is \( n \)-ary, and \( g_1, \ldots, g_m \) are \( n \)-ary for some \( n \));

Rec\((f, g)\) denotes the function obtained from \( f \) and \( g \) by recursion (assuming that \( f \) is \( n \)-ary and \( g \) is \((n+2)\)-ary for some \( n \)).

If we write \( S \) for the function \( x+1 \), then we have, for example, the following plan for the function \( f(x) = x^2 \). We use letters \( g_1, \ldots, g_4 \) to denote intermediate functions.

Plan

<table>
<thead>
<tr>
<th>Step 1. ( g_1 = \text{Sub}(S; U_1^3) )</th>
<th>( g_1(x, y, z) = U_1^3(x, y, z) + 1 = z + 1 ).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2. ( g_2 = \text{Rec}(U_1^1, g_1) )</td>
<td>( g_2(x, 0) = U_1^1(x) = x ), ( g_2(x, y + 1) = g_1(x, y, g_2(x, y)) = g_2(x, y) + 1 ).</td>
</tr>
<tr>
<td>Step 3. ( g_3 = \text{Sub}(g_2; U_1^3, U_2^3) )</td>
<td>( g_3(x, y, z) = g_2(x, z) + x + z ).</td>
</tr>
<tr>
<td>Step 4. ( g_4 = \text{Rec}(0, g_3) )</td>
<td>( g_4(x, 0) = 0 ), ( g_4(x, y + 1) = g_3(x, y, g_4(x, y)) = g_4(x, y) + 1 ).</td>
</tr>
<tr>
<td>Step 5. ( f = \text{Sub}(g_4; U_1^1) )</td>
<td>( f(x) = g_4(x, x) = x^2 ).</td>
</tr>
</tbody>
</table>

Thus a plan is somewhat akin to a program, in that it is a finite and explicit specification of a function.

We now restrict our attention to plans for unary primitive recursive functions. As with programs, we can number these plans in an effective
way, so that we may then define
\[ \theta_n = \text{the unary primitive recursive function} \]
\[ \text{defined by plan number } n. \]
Then \( \theta_0, \theta_1, \theta_2, \ldots \) is an effective enumeration of all unary primitive recursive functions.

From chapter 2 we know that every primitive recursive function is computable. Hence there is a total function \( p \) such that for each \( n \), \( p(n) \) is the number of a program that computes \( \theta_n \); i.e.
\[ \theta_n = \phi_{p(n)}. \]

Now the crucial point is that we can find such a function \( p \) that is computable. We argue informally using Church's theorem.

Recall the proofs of theorems 2.3.1 and 2.4.4. There we showed explicitly how to obtain a program for the function
\[ \text{Sub}(f, g, \ldots, g_m) \]
given programs for \( f, g, \ldots, g_m \); and also, how to obtain a program for the function
\[ \text{Rec}(f, g) \]
given programs for \( f \) and \( g \). In the next section (example 3.1(5)) we use the \( s-m-n \) theorem to show in detail that for any \( n \), there is a computable function \( r \) such that for any \( e \), \( e \) is an index for \( \text{Rec}(\phi_{r(e)}^{(n)}, \phi_{r(e)}^{(n + 1)}) \) is given by \( r(e, e) \); we can do a similar thing for substitution (see exercise 3.2(5a)). We also have explicit programs for the basic functions. Hence, given a plan for a primitive recursive function \( f \) involving intermediate functions \( g_1, \ldots, g_k \), say, we can effectively find programs for \( g_1, g_2, \ldots, g_k \) and finally \( f \). Thus there is an effectively computable function \( p \) such that
\[ \theta_n = \phi_{p(n)}. \]

By Church's thesis, \( p \) is computable.

Now for the payoff! From \( p \) and the universal function \( \phi_{\theta}, \) we can define a total computable function \( g \) that differs from every primitive recursive function \( \theta_n \). We use a diagonal construction as follows:
\[ g(x) = \theta_n(x) + 1 \]
\[ = \phi_{p(n)}(x) + 1 \]
\[ = \theta_n(x) + 1. \]

From this we see immediately that \( g \) is a total function that is not primitive recursive; but \( g \) is computable, by the computability of \( \phi_{\theta} \) and \( p \). □

3. Effective operations on computable functions

In this section we illustrate another important application of the computability of the universal functions, this time in conjunction with the \( s-m-n \) theorem.

Consider the following operations on computable functions or their domains:
(a) combining \( \phi_1 \) and \( \phi_2 \) to form the product \( \phi_1 \phi_2 \);
(b) forming the union \( W \cup W_n \) from \( W \) and \( W_n \).

We are all familiar with a wide variety of operations of a similar kind, usually defined explicitly like these. Is there any sense in which these operations can be thought of as effective operations? Inasmuch as these are operations involving infinite objects (functions or sets), they seem to lie outside the scope of even our informal notion of computability, which implicitly applies only to finite objects. Nevertheless, we will see, for instance, that an index for the function \( \phi_1 \phi_2 \) can be obtained effectively from the indices \( x, y \). In the following examples and exercises we see that many other operations are effective when viewed as operations on indices of the objects involved. (We will return to the topic of effective operations on functions in chapter 10.)

3.1. Examples

1. There is a total computable function \( s(x, y) \) such that for all \( x, y \)
\[ \phi_{s(x,y)} = \phi_1 \phi_2. \]

Proof. Let \( f(x, y, z) = \phi_1(z) \phi_2(z) \)
\[ = \phi_1(x, z) \phi_2(y, z). \]

Thus \( f \) is computable, so by the \( s-m-n \) theorem there is a total computable function \( s(x, y) \) such that \( f(x, y, z) = \phi_{s(x,y)}(z) \); hence
\[ \phi_{s(x,y)} = \phi_1 \phi_2. \]

2. Taking \( g(x) = s(x, x) \), with \( x \) as an example 1, we have \( (\phi_1)^2 = \phi_{s(x,x)}. \)

3. There is a total computable function \( s(x, y) \) such that
\[ W_s(x, y) = W_x \cup W_y. \]

Proof. Let \( f(x, y, z) = \begin{cases} 1 & \text{if } z \in W_x \text{ or } z \in W_y; \\ \text{undefined} & \text{otherwise.} \end{cases} \]

By Church's thesis and the computability of \( \psi_0 \), \( f \) is computable; so there is a total computable function \( s(x, y) \) such that \( f(x, y, z) = \phi_{s(x,y)}(z) \). Then clearly \( W_s(x, y) = W_x \cup W_y. \)
4. Effectiveness of taking inverses. Let \( g(x, y) \) be a computable function as described in exercise 1.5; i.e., such that
   (a) \( g(x, y) \) is defined if and only if \( y \in E_x \),
   (b) if \( y \in E_x \), then \( g(x, y) \in W_y \) and \( \phi_e(g(x, y)) = y \).

By the \( s\-m\-n \) theorem there is a total computable function \( k \) such that \( g(x, y) = \phi_{k(x)}(y) \). Then from (a) and (b) we have
   \[ \begin{align*}
   (a') & \quad W_{k(x)} = \{E_y \mid y \in E_x \}, \\
   (b') & \quad (i) \ E_{k(x)} \subseteq W_y, \\
   & \quad (ii) \ if \ y \in E_x, then \ \phi_e(\phi_{k(x)}(y)) = y.
   \end{align*} \]

Hence, if \( \phi_e \) is injective, then \( \phi_{k(x)} = \phi_e^{-1} \) and \( E_{k(x)} = W_y \).

5. Effectiveness of recursion. Let \( x = (x_1, \ldots, x_n) \) and consider the \( (n+3)\)-ary function \( f \) defined by
   \[ f(e_0, e_2, x, 0) = \phi_e^{(x)}(x), \]
   \[ f(e_0, e_2, x, y + 1) = \phi_e^{(x+2)}(x, y, f(e_0, e_2, x, y)). \]

Then using the universal functions \( \psi^{(x)}_1 \) and \( \psi^{(x+2)}_2 \) to rewrite the expressions on the right, this is a definition by recursion from computable functions, so \( f \) is computable. Moreover, for fixed \( e_0, e_2 \), the function \( g(x, y) = f(e_0, e_2, x, y) \) is the function obtained from \( \phi_e^{(x)} \) and \( \phi_e^{(x+2)} \) by recursion.

By the \( s\-m\-n \) theorem there is a total computable function \( r(e_0, e_2) \) such that
   \[ \phi_e^{(x)}(x, y) = f(e_0, e_2, x, y). \]

Hence \( r(e_0, e_2) \) is an index for the \( (n+1)\)-ary function obtained from \( \phi_e^{(x)} \) and \( \phi_e^{(x+2)} \) by recursion. In the notation of theorem 2.2
   \[ \phi_e^{(x)} = \text{Rec}(\phi_e^{(x)}, \phi_e^{(x+2)}) \]
for all \( e_0, e_2 \).

The following exercises give more examples of the use of the \( s\-m\-n \) theorem in showing that operations are effective on indices.

3.2. Exercises
1. Show that there is a total computable function \( k(e) \) such that for any \( e, \) if \( \phi_e \) is the characteristic function for a decidable predicate \( M(x) \), then \( \phi_{k(e)} \) is the characteristic function for ‘not \( M(x) \)’.
2. Show that there is a total computable function \( k(x) \) such that for every \( x, E_{k(x)} = W_x \).
3. Show that there is a total computable function \( s(x, y) \) such that for all \( x, y, E_{s(x, y)} = E_x \cup E_y \).
4. Suppose that \( f(x) \) is computable; show that there is a total computable function \( k(x) \) such that for all \( x, W_{k(x)} = f^{-1}(W_x) \).

5. Prove the equivalent of example 5 above for the operations of substitution and minimalization, namely:
   (a) \( \text{Fix } n \geq 1; \) there is a total computable function \( s(e_1, \ldots, e_n) \) such that (in the notation of theorem 2.2)
       \[ \phi_{k_s(e_1, \ldots, e_n)}^{(n)} = \text{Sub}(\phi_{e_1}, \phi_{e_2}, \ldots, \phi_{e_n}). \]
   (b) \( \text{Fix } n \geq 1; \) there is a total computable function \( k(e) \) such that for all \( e, \)
       \[ \phi_{k(e)}^{(n)}(x, y) = \mu y(\phi_{k(e+1)}^{(n+1)}(x, y) = 0). \]

(We could extend the notation of theorem 2.2 in the obvious way and write \( \phi_{k(e)}^{(n)} = \text{Min}(\phi_{k(e+1)}^{(n+1)}). \))

Appendix

Computability of the function \( \sigma_n \)

In this appendix we give a formal proof that the function \( \sigma_n \)
defined in the proof of theorem 1.2 is computable (in fact, primitive recursive) thus completing a formal proof of the computability of the universal function \( \psi^{(c)}_1 \).

Theorem.
The function \( \sigma_n \) is primitive recursive.

Proof. For the definition of \( \sigma_n \) and the functions \( c_n \) and \( f_n \) coded by \( \sigma_m \) refer to the proof of theorem 1.2.

We define two functions ‘config’ and ‘\( \text{nxt} \)’ that describe the changes in \( c_n \) and \( f_n \) during computations. Suppose that at some stage during computation under \( P \), the current state is \( \sigma = \pi(c, f) \), and suppose that \( P \) has \( s \) instructions. We can describe the effect of the \( j \)th instruction of \( P \) on the state \( \sigma \) by defining

\[
\text{config}(c, \sigma) = \begin{cases} 
\text{the new configuration} & \text{if } 1 \leq j \leq s, \\
\text{after the } j \text{th instruction of } P \text{ has been obeyed,} \\
\text{of } P \text{ has been obeyed,} \\
\text{and } \sigma & \text{otherwise.} \\
\end{cases}
\]

\[
\text{nxt}(c, \sigma) = \begin{cases} 
\text{the number of the } j \text{th instruction for the} & \text{if } 1 \leq j \leq s, \\
\text{next computation, after the} & \text{and this next} \\
\text{instruction exists in } P, & \text{instruction} \\
\text{has been executed on the} & \text{configuration } c, \\
\text{configuration } c. & \text{otherwise.}
\end{cases}
\]
Now \( \sigma_n \) can be obtained from \( \text{config} \) and \( \text{nxt} \) by the following recursion equations:

\[
\sigma_n(e, x, 0) = \pi(2^1 \cdot 3^5 \cdots p_x^{e_x}),
\]

\[
\sigma_n(e, x, t + 1) = \pi(\text{config}(e, \sigma_n(e, x, t)), \text{nxt}(e, \sigma_n(e, x, t))).
\]

Thus, \( \sigma_n \) is primitive recursive if \( \text{config} \) and \( \text{nxt} \) are primitive recursive; we proceed to show that they are.

We must be careful now to distinguish between the code number \( \beta(I) \) of an instruction \( I \) and its number in any program in which it occurs (i.e., the number \( j \) such that \( I \) is the \( j \)th instruction). We will always use the term code number when \( \beta(I) \) is intended.

It is sufficient to establish that the following four functions are primitive recursive:

1. \( \ln(e) = \text{the number of instructions in program } P_e; \)
2. \( \text{gn}(e, j) = \begin{cases} \text{the code number of the } j \text{th instruction in } P_e, & \text{if } 1 \leq j \leq \ln(e), \\ 0 & \text{otherwise}; \end{cases} \)
3. \( \text{ch}(e, x) = \text{the configuration resulting when the configuration } c \text{ is operated on by the instruction with code number } x; \)
4. \( \nu(c, j, x) = \begin{cases} \text{the } j \text{th instruction in a program,} & \text{if } j > 0, \\ 0 & \text{otherwise.} \end{cases} \)

(The 'next instruction for the computation' here is as defined in chapter 1 § 2, so \( f' = j + 1 \) or, if \( f \) is a jump instruction \( J(m_1, m_2, q) \) we may have \( f' = q \).)

If these four functions are primitive recursive, then remembering that \( \sigma = \pi(c, f) \) where \( e = \pi_1(\sigma) \) and \( f = \pi_2(\sigma) \) we have

\[
\text{config}(e, \sigma) = \begin{cases} \text{ch}(\pi_1(\sigma), \text{gn}(e, \pi_2(\sigma))) & \text{if } 1 \leq \pi_2(\sigma) \leq \ln(e), \\ \pi_1(\sigma) & \text{otherwise.} \end{cases}
\]

Thus \( \text{config} \) and \( \text{nxt} \) are primitive recursive, by the methods of chapter 2.

It remains to show that the functions (1)-(4) above are primitive recursive. A sequence of auxiliary functions is needed to decode the code numbers of programs and instructions. We use freely the standard functions and techniques of chapter 2 §§ 1-4, together with the functions defined in chapter 4 § 1 for coding instructions and programs.

(5) The functions \( \alpha(i, x), \beta(i, x), \gamma(i, x) \) of exercise 2-4.16(5) are primitive recursive.

Proof. (i) \( x = \sum_{k \geq 1} \alpha(i, x); \) so we have \( q \beta(2^i, x) = \alpha(i, x) + \alpha(i + 1, x) \ldots \) and hence \( \alpha(i, x) = \beta(q \beta(2^i, x)). \)

(ii) \( l(x) = \text{number of } i \text{ such that } \alpha(i, x) = 1; \) hence

\[
l(x) = \sum_{i \geq 1} \alpha(i, x).
\]

(iii) If \( x > 0, \beta(i, x) = \sum_{k \geq i} \beta(k, x); \) thus, if \( 1 \leq i \leq l(x), \) then \( \beta(i, x) \) is the \( i \)th index \( k \) such that \( \alpha(k, x) = 1. \) Hence

\[
\beta(i, x) = \begin{cases} \mu \gamma \leq x \left( \sum_{k \geq 1} \alpha(k, x) = i \right) & \text{if } 1 \leq i \leq l(x) \text{ and } x > 0, \\ 0 & \text{otherwise.} \end{cases}
\]

(iv) From the definition:

\[
\alpha(i, x) = \beta(i, x) \quad (i = 0, 1)
\]

\[
\alpha(i + 1, x) = \beta(i + 1, x) - \beta(i, x) + 1 \quad (i \geq 1)
\]

From the above explicit formulae, using the techniques of chapter 2, these functions are all primitive recursive.

(6) The functions \( \ln(e) \) and \( \text{gn}(e, j) \) are primitive recursive.

Proof. From the definitions of the coding function \( \gamma: \)

\[
\ln(e) = l(e + 1),
\]

\[
\text{gn}(e, j) = a(j, e + 1),
\]

where \( l \) and \( a \) are the functions in (5).

(7) There are primitive recursive functions \( u, u_1, u_2, v_1, v_2, v_3 \) such that:

- if \( x = \beta(2^m), \text{ then } u(z) = m, \)
- if \( x = \beta(S(m)), \text{ then } u(z) = m, \)
- if \( x = \beta(T(m, m_2)), \text{ then } u_1(z) = m_1, \text{ and } u_2(z) = m_2, \)
- if \( z = \beta(J(m_1, m_2, q)), \) then \( v_1(z) = m_1, v_2(z) = m_2, \) and \( v_3(z) = q. \)
Proof. From the definition of $\beta$, and writing $(x/4)$ for $q(t, x)$, take

\[ u(z) = (x/4) + 1, \]
\[ u_1(z) = \pi_1((x/4)) + 1, \]
\[ u_2(z) = \pi_2((x/4)) + 1, \]
\[ v_1(z) = \pi_1(\pi_2((x/4))) + 1, \]
\[ v_2(z) = \pi_2(\pi_1((x/4))) + 1, \]
\[ v_3(z) = \pi_3((x/4)) + 1. \]

(8) The following functions are primitive recursive:

(i) \( \text{zero}(c, m) \) = the change in the configuration \( c \)

\[ = q((\beta_{\text{inst}}^{(m)}, c)). \]

(ii) \( \text{suc}(c, m) \) = the change in the configuration \( c \)

\[ = c_{\text{inst}}. \]

(iii) \( \text{transfer}(c, m, n) \) = the change in the configuration \( c \)

\[ = q((\beta_{\text{inst}}^{(n)}, c_{\text{inst}}^{(m)})). \]

(9) The function \( \text{ch}(c, z) \) (defined in (3) above) is primitive recursive. \( \text{Proof}. \)

\[ \begin{align*}
\text{zero}(c, u(z)) & \quad \text{if rm}(4, z) = 0 \text{ (i.e. } z \text{ is the code of a zero instruction)}, \\
\text{suc}(c, u(z)) & \quad \text{if rm}(4, z) = 1 \text{ (i.e. } z \text{ is the code of a successor instruction)}, \\
\text{ch}(c, z) & = \text{zero}(c, u(z)) \quad \text{if rm}(4, z) = 0 \text{ (i.e. } z \text{ is the code of a zero instruction)}, \\
& \quad \text{transfer}(c, u_1(z), u_2(z)) \quad \text{if rm}(4, z) = 2 \text{ (i.e. } z \text{ is the code of a transfer instruction)}, \\
& \quad \text{otherwise.}
\end{align*} \]

(10) The function \( \nu(c, f, z) \) (defined in (4) above) is primitive recursive. \( \text{Proof}. \)

\[ \nu(c, f, z) = \begin{cases} 
j - 1 & \text{if rm}(4, z) \neq 3 \\
& \text{(i.e. } z \text{ is the code of an arithmetic instruction)}, \\
& \text{if rm}(4, z) = 3 \\
& \text{(i.e. } z \text{ is the code of a jump instruction).}
\end{cases} \]

From this definition by cases, we see that \( \nu \) is primitive recursive.

We have now shown that the functions (1)-(4) above are primitive recursive, so the proof of the theorem is complete. \( \Box \)
6
Decidability, undecidability and partial decidability

In previous chapters we have noted several decidable problems, but so far we have encountered only one explicit example of undecidability: the problem \( \phi_e \) is total (Theorem 5.2.1). It is of considerable interest to identify decidable and undecidable problems; the latter, particularly, indicate the limitations of computability, and hence demonstrate the theoretical limits to the power of real world computers.

In this chapter the emphasis is largely on undecidability. In §1 we give a survey of undecidable problems arising in the theory of computability itself, and discuss some methods for establishing undecidability. Sections 2–5 are devoted to a sample of decidable and undecidable problems from other areas of mathematics; these sections will not be needed in later chapters and may be omitted. In the final section we discuss partial decidability, a notion closely related to decidability.

Let us recall from Chapter 1 that a predicate \( M(x) \) is said to be decidable if its characteristic function \( c_M \), given by

\[
c_M(x) = \begin{cases} 1 & \text{if } M(x) \text{ holds,} \\ 0 & \text{if } M(x) \text{ does not hold,} \end{cases}
\]

is computable. This is the same as saying that \( M(x) \) is recursive (see Chapter 3 §2). The predicate \( M(x) \) is undecidable if it is not decidable. In the literature all of the following phrases are used to mean that \( M(x) \) is decidable.

- \( M(x) \) is recursively decidable.
- \( M(x) \) has a recursive decision problem.
- \( M(x) \) is solvable.
- \( M(x) \) is recursively solvable.
- \( M(x) \) is computable.

An algorithm for computing \( c_M \) is called a decision procedure for \( M(x) \).

1. Undecidable problems in computability

Most proofs of undecidability rest on a diagonal construction, as in the following important example.

1.1 Theorem

\( x \in W_e \) (or, equivalently, \( \phi_e(x) \) is defined), or \( P_e(x) \), or \( \psi_e(x) \) is defined is undecidable.

Proof. The characteristic function \( f \) of this problem is given by

\[
f(x) = \begin{cases} 1 & \text{if } x \in W_e, \\ 0 & \text{if } x \notin W_e. \end{cases}
\]

Suppose that \( f \) is computable; we shall obtain a contradiction. Specifically, we make a diagonal construction of a computable function \( g \) such that \( \text{Dom}(g) \neq W_e = \text{Dom}(\phi_e) \) for every \( x \); this is obviously contradictory.

The diagonal motto tells us to ensure that \( \text{Dom}(g) \) differs from \( W_e \) at \( x \); so we aim to make

\[
x \in \text{Dom}(g) \iff x \notin W_e.
\]

Let us define \( g \), then, by

\[
g(x) = \begin{cases} 0 & \text{if } x \in W_e \text{ (i.e. if } f(x) = 0), \\ \text{undefined} & \text{if } x \notin W_e \text{ (i.e. if } f(x) = 1). \end{cases}
\]

Since \( f \) is computable, then so is \( g \) (by Church’s thesis); so we have our contradiction. (To see this in detail: since \( g \) is computable take \( m \) such that \( g = \phi_m \); then \( m \in W_m \Rightarrow m \in \text{Dom}(g) \Rightarrow m \notin W_m \), a contradiction.)

We conclude that \( f \) is not computable, and so the problem \( x \in W_e \) is undecidable.

Note that this theorem does not say that we cannot tell for any particular number \( a \) whether \( \phi_e(a) \) is defined. For some numbers this is quite simple; for instance, if we have written a program \( P \) that computes a total function, and \( P = P_m \) then we know immediately that \( \phi_m(a) \) is defined. What the theorem says is that there is no single general method for deciding whether \( \phi_e(a) \) is defined; i.e. there is no method that works for every \( x \).

An easy corollary to the above result is

1.2 Corollary

There is a computable function \( h \) such that the problems \( x \in \text{Dom}(h) \) and \( x \in \text{Ran}(h) \) are both undecidable.
Proof. Let

\[ h(x) = \begin{cases} 1 & \text{if } x \in W^c, \\ \text{undefined} & \text{if } x \notin W. \end{cases} \]

Then \( h \) is computable, by Church's thesis and the computability of the universal function \( \psi_t \) (or, formally, we have that \( h(x) = x \psi_t(x, x) \)) which is computable by substitution. Clearly we have \( x \in \text{Dom}(h) \iff x \in W \iff x \in \text{Ran}(h) \), so the problems 'x \in \text{Dom}(h)' and 'x \in \text{Ran}(h)' are undecidable.

Another important undecidable problem is derived easily from theorem 1.1.

1.3. Theorem (the Halting problem)

The problem '\( \phi_e(\gamma) \) is defined' (or, equivalently '\( \nu_e(\gamma) \) or '\( \gamma \in W_e \)') is undecidable.

Proof. Arguing informally, if the problem '\( \phi_e(\gamma) \) is defined' is decidable then so is the problem '\( \phi_e(x) \) is defined', which is if anything easier. But this contradicts theorem 1.1.

Giving this argument in full detail, let \( g \) be the characteristic function for '\( \phi_e(\gamma) \) is defined'; i.e.

\[ g(x, \gamma) = \begin{cases} 1 & \text{if } \phi_e(\gamma) \text{ is defined}, \\ 0 & \text{if } \phi_e(\gamma) \text{ is not defined}. \end{cases} \]

If \( g \) is computable, then so is the function \( f(x, \gamma) = g(x, \gamma) \); but \( f \) is the characteristic function of '\( x \in W_e \)', and is not computable by theorem 1.1. Hence \( g \) is not computable; so '\( \phi_e(\gamma) \) is defined' is undecidable.

Theorem 1.3 is often described as the Unsolvability of the Halting problem (for URM programs); there is no effective general method for discovering whether a given program running on a given input eventually halts. The implication of this for the theory of computer programming is obvious: there can be no perfectly general method for checking programs to see if they are free from possible infinite loops.

The undecidable problem '\( x \in W_e \)' of theorem 1.1 is important for several reasons. Among these is the fact that many problems can be shown to be undecidable by showing that they are at least as difficult as this one. We have already done this in a simple way in showing that the Halting problem is undecidable (theorem 1.3); this process is known as reducing one problem to another.

Speaking generally, consider a problem \( M(x) \). Often we can show that a solution to the general problem \( M(x) \) would lead to a solution to the particular problem '\( x \in W_e \)'. Then we say that the problem '\( x \in W_e \)' is reduced to the problem \( M(x) \). In other words, we can give a decision procedure for '\( x \in W_e \)' if only we could find one for \( M(x) \). In this case, the decidability of \( M(x) \) implies the decidability of '\( x \in W_e \)', from which we conclude immediately that \( M(x) \) is undecidable.

The \( s-m-n \) theorem is often useful in reducing '\( x \in W_e \)' to other problems, as illustrated in the proof of the next result.

1.4. Theorem

The problem '\( \phi_e = 0 \)' is undecidable.

Proof. Consider the function \( f \) defined by

\[ f(x, \gamma) = \begin{cases} 0 & \text{if } x \in W, \\ \text{undefined} & \text{if } x \notin W. \end{cases} \]

We have defined \( f \) anticipating that we shall use the \( s-m-n \) theorem; thus we are thinking of \( x \) as a parameter, and are concerned about the functions \( g_e \) where \( g_e(x) = f(x, x) \). We have actually designed \( f \) so that \( g_e(x) = 0 \iff x \in W \).

By Church's thesis (or by substitution using 0 and \( \psi_t \)) \( f \) is computable; so there is a total computable function \( k(x) \) given by the \( s-m-n \) theorem such that \( f(x, \gamma) = \phi_{k(x)}(\gamma) \); i.e., \( \phi_{k(x)} = g_e \). Thus from the definition of \( f \) we see that

\[ (*) \quad x \in W_e \iff \phi_{k(x)} = 0. \]

Hence, a particular question Is \( x \in W_e \)? can be settled by answering the question Is \( \phi_{k(x)} = 0 \)? We have thus reduced the general problem '\( x \in W_e \)' to the general problem '\( \phi_e = 0 \)'; the former is undecidable, hence so is the latter, as was to be proved.

Let us present the final part of this argument in more detail as it is the first example of its kind. Let \( g \) be the characteristic function of '\( \phi_e = 0 \)'; i.e.,

\[ g(x) = \begin{cases} 1 & \text{if } \phi_e = 0, \\ 0 & \text{if } \phi_e \neq 0. \end{cases} \]

Suppose that \( g \) is computable; then so is the function \( h(x) = g(k(x)) \). But from (*) above we have

\[ h(x) = \begin{cases} 1 & \text{if } \phi_{k(x)} = 0; \text{ i.e. } x \in W, \\ 0 & \text{if } \phi_{k(x)} \neq 0; \text{ i.e. } x \notin W. \end{cases} \]
So by theorem 1.1 $h$ is not computable. Hence $g$ is not computable, and the problem \( \phi_x = 0 \) is undecidable. \( \square \)

From theorem 1.4 we can see that there are inherent limitations when it comes to checking the correctness of computer programs; this theorem shows that there can be no perfectly general effective method for checking whether a program will compute the zero function. By adapting the proof of theorem 1.4 we can see that the same is true for any particular computable function (see exercise 1.8(i) below).

The following easy corollary to theorem 1.4 shows that the question of whether two programs compute the same unary function is undecidable. Again there are obvious implications for computer programming theory.

1.5. Corollary

The problem \( \phi_x = \phi_y \) is undecidable.

Proof. We can easily see that this is a harder problem than the problem \( \phi_x = 0 \).

Let $c$ be a number such that $\phi_x = 0$; if $f(x, y)$ is the characteristic function of the problem $\phi_x = \phi_y$, then the function $g(x) = f(x, c)$ is the characteristic function of $\phi_x = 0$. By theorem 1.4, $g$ is not computable, so neither is $f$. Thus \( \phi_x = \phi_y \) is undecidable. \( \square \)

We use the \( s-m-n \) theorem again to reduce the problem \( x \in W_x \) in the following results.

1.6. Theorem

Let $c$ be any number. The following problems are undecidable:

(a) (the Input or Acceptance problem) \( c \in W_x \) (equivalently, \( P(c) \) or \( c \in \text{Dom}(\phi_x) \)),

(b) (the Output or Printing problem) \( c \in E_x \) (equivalently, \( c \in \text{Ran}(\phi_x) \)).

Proof. We are able to reduce \( x \in W_x \) to these problems simultaneously. Consider the function $f(x, y)$ given by

\[
    f(x, y) = \begin{cases} 
    y & \text{if } x \in W_x \\
    \text{undefined} & \text{otherwise}.
    \end{cases}
\]

(With the \( s-m-n \) theorem in mind, we are concerned about the functions $g_x$ where $g_x(y) = f(x, y)$; we have designed $f$ so that $c \in \text{Dom}(g_x) \Leftrightarrow x \in W_x \Leftrightarrow c \in \text{Ran}(g_x)$.) By Church's thesis $f$ is computable, and so the \( s-m-n \) theorem provides a total computable function $k$ such that $f(x, y) = \phi_k(k(x))$. From the definition of $f$ we see that

\[
    x \in W_x \Rightarrow W_{k(x)} = E_{k(x)} = \emptyset, \text{ so } c \notin W_{k(x)} \text{ and } c \in E_{k(x)};
\]

and

\[
    x \notin W_x \Rightarrow W_{k(x)} = E_{k(x)} = \mathbb{N}, \text{ so } c \notin W_{k(x)} \text{ and } c \notin E_{k(x)}.
\]

Thus we have reduced the problem \( x \in W_x \) to each of the problems \( c \in W_x \) and \( c \in E_x \).

Completing the proof of (a) in detail, we see that if $g$ is the characteristic function of \( c \in W_x \), then

\[
    g(k(x)) = \begin{cases} 
    1 & \text{if } x \in W_x \\
    0 & \text{if } x \notin W_x.
    \end{cases}
\]

This function is not computable (theorem 1.1), so $g$ cannot be computable. Hence \( c \in W_x \) is undecidable.

A detailed proof of (b) is similar. \( \square \)

We conclude this section with a very general undecidability result, from which theorems 1.4 and 1.6 follow immediately. It is another use of the \( s-m-n \) theorem to reduce \( x \in W_x \).

1.7. Theorem (Rice's theorem)

Suppose that $\mathcal{B} \subseteq \mathcal{E}_1$ and $\mathcal{B} \neq \emptyset$, $\mathcal{E}_1$. Then the problem \( \phi_x \in \mathcal{B} \) is undecidable.

Proof. From the algebra of decidability (theorem 2.4.7) we know that \( \phi_x \in \mathcal{B} \) is decidable iff \( \phi_x \in \mathcal{E}_1 \cap \mathcal{B} \) is decidable; so we may assume without loss of generality that the function $f_E$ that is nowhere defined does not belong to $\mathcal{B}$ (if not, prove the result for $\mathcal{E}_1(\mathcal{B})$).

Choose a function $g \in \mathcal{B}$. Consider the function $f(x, y)$ defined by

\[
    f(x, y) = \begin{cases} 
    g(y) & \text{if } x \in W_x \\
    \text{undefined} & \text{if } x \notin W_x.
    \end{cases}
\]

The \( s-m-n \) theorem provides a total computable function $k(x)$ such that $f(x, y) = \phi_{k(x)}(y)$. Thus we see that

\[
    x \in W_x \Rightarrow \phi_{k(x)} = g, \text{ i.e. } \phi_{k(x)} \in \mathcal{B};
\]

\[
    x \notin W_x \Rightarrow \phi_{k(x)} = f_E, \text{ i.e. } \phi_{k(x)} \notin \mathcal{B}.
\]

So we have reduced the problem \( x \in W_x \) to the problem \( \phi_x \in \mathcal{B} \) using the computable function $k$. In the standard way we conclude that \( \phi_x \in \mathcal{B} \) is undecidable. \( \square \)
Theorem 1.4, for example, is obtained immediately from Rice's theorem by taking $\mathcal{R} = \{0\}$, and theorem 1.6(a) by taking $\mathcal{R} = \{g \in \mathcal{C} : c \in \text{Dom}(g)\}$. Rice's theorem may be similarly applied in several of the exercises below.

1.8. **Exercises**

1. Show that the following problems are undecidable.
   
   (a) $x \in E'$ (Hint: Either use a direct diagonal construction, or reduce $x \in W_2$ to this problem using the $x \sim m \sim n$ theorem.)
   
   (b) $W_1 = W_2'$ (Hint: Reduce $\phi_1$ is total to this problem.)
   
   (c) $\phi_2(x) = 0$
   
   (d) $\phi_2(x) = 0'$
   
   (e) $x \in E_1$
   
   (f) $\phi_4$ is total and constant,
   
   (g) $W_2 \sim O'$
   
   (h) $E_2$ is infinite.
   
   (i) $\phi_5 = g'$, where $g$ is any fixed computable function.

2. Show that there is no total computable function $f(x, y)$ with the following property: if $P_2(y)$ stops, then it does so in $f(x, y)$ or fewer steps. (Hint: Show that if such a function exists, then the Halting problem is decidable.)

**Decidability and undecidability in other areas of mathematics.** In many areas of mathematics there arise general problems for which the informal idea of decidability is meaningful. Generally such problems involve finite objects from a particular field of study. The idea of decidability of some property involving these objects can always be made precise using a suitable coding by natural numbers.

Much research has been directed towards identifying both decidable and undecidable problems in a variety of mathematical situations: in the next sections we give a small sample of the results that have been obtained.

2. **The word problem for groups**

   Suppose that $G$ is a group with identity element $1$, and that $G$ is generated by a set of elements $S = \{g_1, g_2, g_3, \ldots\} \subseteq G$. A word on $S$ is any expression such as $g_1^{-1}g_2g_3g_4$ involving the elements of $S$ and the group operations. Each word represents an element of $G$, and to say that $G$ is generated by $S$ means that every element of $G$ is represented by some word on $S$.

   The word problem for $G$ (relative to $S$) is the problem of deciding for which words $w$ on $S$ it is the case that $w = 1$.

   There are many groups with decidable word problem: for example any finite group (with $S$ finite, of course). For many years mathematicians searched for an example of a *finitely presented* group with undecidable word problem. Eventually it was shown by Novikov in 1955 and Boone in 1957 that such groups do exist. Proofs of the Novikov–Boone Theorem are beyond the scope of this survey: the reader is referred to expositions in Rotman [1965] or Manin [1977].

   Group theory, and modern algebra in general, abounds with interesting decidable and undecidable problems; a great many of them involve properties of words or generators akin to the basic word problem for groups.

3. **Diophantine equations**

   Suppose that $p(x_1, x_2, \ldots, x_n)$ is a polynomial in the variables $x_1, \ldots, x_n$ with integer coefficients. Then the equation
   
   $$p(x_1, x_2, \ldots, x_n) = 0$$
   
   for which integer solutions are sought is called a diophantine equation.

   Diophantine equations do not always have solutions: for instance the equation $x^2 - 2 = 0$.

   Hilbert's tenth problem, posed in 1900, asks whether there is an effective procedure that will determine whether any given diophantine equation has a solution. It was shown in 1970 by Y. Matiyasevich that there is no such procedure: his proof was the culmination of earlier work by M. Davis, J. Robinson and H. Putnam.

   Actually Matiyasevich established rather more than the unsolvability of Hilbert's tenth problem; the full Matiyasevich theorem and its application to Hilbert's tenth problem are discussed in § 6. For complete details consult Davis [1973] or Manin [1977], or Bell & Machover [1977].

---

1. The reader with no knowledge of group theory should omit this section.
4. Sturm's algorithm

To redress the emphasis on undecidability in the previous two sections, we now mention a theorem of Sturm that gives us positive results for computability and decidability in connection with the zeros of polynomials.

4.1. Sturm's theorem

Let \( p(x) \) be a real polynomial, and let \( p_0, p_1, \ldots, p \) be the sequence of polynomials given by

(a) \( p_0 = 0 \),
(b) \( p_1 = p' \) (the derivative of \( p \)),
(c) for \( 0 < i < r \), there is a polynomial \( q \) such that \( p_{i-1} = p_{i-2} - p_{i-1}q \) with \( p_{i-2} \neq 0 \) and degree \( p_{i-1} < \) degree \( p_i \) (so that \( q \) and \( p_{i-1} \) are the quotient and remainder respectively when \( p_{i-1} \) is divided by \( p_i \)),
(d) \( p_{r-1} = p_r \).

For any real number \( c \) denote by \( \delta(c) \) the number of sign changes in the sequence \( p_0(c), p_1(c), \ldots, p_r(c) \) (ignoring zeros).

Suppose that \( a, b \) are real numbers that are not zeros of \( p(x) \), and \( a < b \). Then the number of zeros of \( p(x) \) in the interval \( [a, b] \) is \( \delta(a) - \delta(b) \), (each zero being counted once only).

This is not the place to give a proof of Sturm's theorem, which the reader may find clearly expounded in Cohn [1977] or Van der Waerden [1949]. From our point of view, Sturm's theorem is interesting because of the algorithm it embodies. It gives us positive results about the computability of the number of zeros of a polynomial, and the decidability of statements about zeros of polynomials.

To frame such results, we must restrict attention to polynomials over the rational numbers, denoted by \( \mathbb{Q} \), so that the objects we are dealing with are finite. Thus we are thinking in terms of computability over the domain \( \mathbb{Q} \) (which can be defined in terms of computability on \( \mathbb{N} \) by the usual coding device); note that a polynomial \( p(x) \) with coefficients in \( \mathbb{Q} \) is essentially a sequence of rational numbers.

A sample of the results that follow from Sturm's theorem is the following.

4.2. Theorem

(a) There is an effective procedure for calculating the number of real zeros of a polynomial over \( \mathbb{Q} \);
(b) The predicate \( p \) has a zero in \( [a, b] \) is decidable, where \( p \) denotes a polynomial over \( \mathbb{Q} \) and \( a, b \in \mathbb{Q} \).

Proof. Given any polynomial \( p(x) \), the polynomials \( p_0, p_1, \ldots, p \) defined in Sturm's theorem may be found effectively by using the standard rules for differentiation and the division algorithm for polynomials.

For (a), it is a routine matter to find for any polynomial \( p(x) \) a rational number \( M > 0 \) such that all the zeros of \( p \) lie in the interval \( [-M, M] \). In fact, if \( p(x) = a_nx^n + a_{n-1}x^{n-1} + \ldots + a_0 \), the number

\[
M = 1 - \frac{1}{|a_n|}(|a_0 - \ldots - |a_{n-1}|)
\]
suffices. Then by Sturm's theorem the number of zeros of \( p \) is \( \delta(-M) - \delta(M) \) which may be calculated effectively.

For (b), suppose that we are given a polynomial \( p \) and rationals \( a, b \). To decide whether \( p \) has a zero in \( [a, b] \), first calculate \( p(a) \) and \( p(b) \); if neither of these is zero, calculate \( \delta(a) - \delta(b) \) and apply Sturm's theorem.

Of course, Sturm's theorem can be used to show that many other questions about polynomials over \( \mathbb{Q} \) are computable or decidable.

4.3. Exercise

Show that there is an effective procedure, given a polynomial \( p \) and rational numbers \( a, b \), for finding the number of zeros of \( p \) in \( [a, b] \). (Remember that \( a \) or \( b \) may be zeros of \( p \).)

5. Mathematical logic

Early investigations into the idea of effective computability were very much linked with the development of mathematical logic, because decidability was regarded as a basic question about any formalisation of mathematics. We shall describe some of the results that have been obtained in this area, in general terms that do not assume any acquaintance with mathematical logic. (The reader interested to learn the basics of this subject may consult one of the many introductory texts, such as Margaris [1966].)

The simplest logical system reflecting something of mathematical reasoning is the propositional calculus. In this calculus compound statements are formed from basic propositions using symbols for the logical connectives 'not', 'and', 'or', and 'implies'. It is quite easy, once the
propositional calculus has been carefully defined, to see that it is decidable. By this we mean that there is an effective procedure for deciding whether a statement \( \varphi \) of the calculus is (universally) valid; i.e. true in all possible situations. The method of truth tables gives an algorithm for this that will be familiar to many readers.

A logical system that has greater expressive power than the propositional calculus is the (first-order) predicate calculus: using the language of this calculus it is possible to formalise a great deal of mathematics. The basic statements are formed from symbols representing individual objects (or elements) and predicates and functions of them. The compound statements are formed using the logical symbols of the propositional calculus together with \( \forall \) and \( \exists \).

There is a precise notion of a proof of a statement of the predicate calculus, such that a statement is provable if and only if it is valid. In 1936 Church showed that provability (and hence validity) in the predicate calculus is undecidable, unlike the simpler propositional calculus. (This result was regarded by Hilbert as the most fundamental undecidability result for the whole of mathematics.)

We can use the URM to give an easy proof of the undecidability of validity, although this calls upon a certain familiarity with the predicate calculus. We advise the reader who does not have a rudimentary knowledge of predicate logic to omit the proof that we now sketch.

5.1. \textbf{Theorem}

Validity in the first-order predicate calculus is undecidable.

\textbf{Proof.} (Not advised for strangers to the predicate calculus.)

Let \( P \) be a program in standard form having instructions \( I_1, \ldots, I_n \) and let \( u = \rho(P) \) (as defined in chapter 2 §2). We use the following symbols of the predicate calculus.

- \( \alpha \) a symbol for an individual,
- \( \gamma \) a symbol for a unary function (whose value at \( x \) is \( x' \)),
- \( R \) a symbol for a \((n+1)\)-ary relation,
- \( x_1, x_2, \ldots, x_n \) symbols for variable individuals.

The interpretation we have in mind is that \( 0 \) represents the number 0, \( ' \) represents the function \( x+1 \), and \( R \) represents the possible states of a computation under \( P \). Thus if we write 1 for 0, 2 for 0', etc. the statement

\[
R(r_1, \ldots, r_n, k)
\]

where \( r_1, \ldots, r_n, k \in \mathbb{N} \) means that the state

\[
\begin{array}{cccccccc}
& & & & & & & \\
& & & & & & & \\
& & & & & & & \\
\end{array}
\]

occurs in the computation.

Now for each instruction \( I_i \) we can write down a statement \( \tau_i \) of the predicate calculus that describes the effect of \( I_i \) on states, using the symbol \( \wedge \) for 'and' and \( \rightarrow \) for 'implies':

\( (a) \) if \( I_i = Z(n) \) let \( \tau_i \) be the statement

\[
\forall x_1, \ldots, x_n. R(x_1, \ldots, x_n, 0) \rightarrow R(x_1, \ldots, x_n, 1).
\]

\( (b) \) if \( I_i = S(n) \) let \( \tau_i \) be the statement

\[
\forall x_1, \ldots, x_n. R(x_1, \ldots, x_n, 0) \rightarrow R(x_1, \ldots, x_n, 1).
\]

\( (c) \) if \( I_i = T(m, n) \) let \( \tau_i \) be the statement

\[
\forall x_1, \ldots, x_n. R(x_1, \ldots, x_n, 0) \rightarrow R(x_1, \ldots, x_n, 1).
\]

\( (d) \) if \( I_i = J(m, n, q) \) let \( \tau_i \) be the statement

\[
\forall x_1, \ldots, x_n. R(x_1, x_2, \ldots, x_n, 0) \rightarrow (x_m = x_n \rightarrow R(x_1, \ldots, x_n, q))
\]

\( \wedge (x_m = x_n \rightarrow R(x_1, \ldots, x_n, 1)) \).

Now for any \( a \in \mathbb{N} \) let \( \sigma_a \) be the statement

\[
(\sigma_0 \wedge \tau_1 \wedge \ldots \wedge \sigma_a \wedge R(a, 0, \ldots, 0, 1)) \rightarrow \exists x_1, \ldots, \exists x_n R(x_1, \ldots, x_n, a + 1),
\]

where \( \tau_0 \) is the statement \( \forall x \forall y ((x' = y' \rightarrow y = x) \wedge x \neq 0) \). (This ensures that in any interpretation, if \( m, n \in \mathbb{N} \) and \( m = n \) then \( m = n \).

The statement \( R(a, 0, \ldots, 0, 1) \) corresponds to a starting state

\[
\begin{array}{cccccccc}
& & & & & & & \\
& & & & & & & \\
& & & & & & & \\
\end{array}
\]

and any statement \( R(x_1, \ldots, x_n, s + 1) \) corresponds to a halting state (since there is no instruction \( I_i \)). Thus we shall see that

\( (*) \quad P(a) \Downarrow \Leftrightarrow \sigma_a \) is valid.

Suppose first that \( P(a) \Downarrow \), and that we have a structure in which \( \tau_0, \ldots, \tau_a \) and \( R(a, 0, \ldots, 0, 1) \) hold. Using the statements \( \tau_0, \ldots, \tau_a \) we find that each of the statements \( R(r_1, \ldots, r_n, k) \) corresponding to the successive states in the computation also holds. Eventually we find that a halting statement \( R(b_1, \ldots, b_n, s + 1) \) holds, for some \( b_1, \ldots, b_n \in \mathbb{N} \), and hence \( \exists x_1, \ldots, \exists x_n R(x_1, \ldots, x_n, s + 1) \) holds. Thus \( \sigma_a \) is valid.

\footnote{This is described by saying that the notion of provability is complete, and is the content of Gödel's incompleteness theorem.}
Conversely, if \( \sigma \) is valid, it holds in particular in the structure \( \mathbb{N} \) with the predicate symbol \( R \) interpreted by the predicate \( R_n \) where

\[
R_n(a_1, \ldots, a_n, k) = \text{At some stage in the computation } P(a) \text{ the registers contain } a_1, a_2, \ldots, a_n, 0, 0, \ldots \text{ and the next instruction is } I_k.
\]

Then \( \tau_0, \ldots, \tau_n \), and \( R(a, 0, \ldots, 0, 0) \) all hold in this structure, hence so does \( \exists x_1 \ldots \exists x_n R(x_1, \ldots, x_n, s + 1) \). Therefore \( P(a) \).

If we take \( P \) to be a program that computes the function \( \psi_0(x, y) \), the equivalence (*) gives a reduction of the problem \( x \in W_n \) to the problem '\( \sigma \) is valid'. Hence the latter is undecidable.

The field of mathematical logic abounds with decidability and undecidability results. A common type of problem that arises is whether a statement is true in all mathematical structures of a certain kind. It has been shown, for example, that the problem

'\( \sigma \) is a statement that is true in all groups'

is undecidable (here \( \sigma \) is a statement of the first-order predicate language appropriate to groups), whereas the problem

'\( \sigma \) is a statement that is true in all abelian groups'

is decidable. (We say that the first-order theory of groups is undecidable whereas the first-order theory of abelian groups is decidable.) It was shown by Tarski [1951] that the problem

'\( \sigma \) is true in the field of real numbers'

is decidable. On the other hand, many problems connected with the formalisation of ordinary arithmetic on the natural numbers are undecidable, as we shall see in chapter 8.

For further examples and proofs of decidability and undecidability results in logic the reader should consult books such as Tarski, Mostowski & Robinson [1953], or Boolos & Jeffrey [1974].

6. Partially decidable predicates

Although the predicate '\( x \in W_n \)' has non-computable characteristic function, the following function connected with this problem is computable:

\[
f(x) = \begin{cases} 1 & \text{if } x \in W_n, \\ \text{undefined} & \text{if } x \not\in W_n. \end{cases}
\]

If we continue to think of 1 as a code for Yes, then any algorithm for \( f \) is a procedure that gives answer Yes when \( x \in W_n \) but goes on for ever when \( x \not\in W_n \) does not hold. Such a procedure is called a partial decision procedure for the problem '\( x \in W_n \)', and we say that this problem or predicate is partially decidable.

Many undecidable predicates turn out to be partially decidable: let us formulate the general definition.

6.1. Definition

A predicate \( M(x) \) of natural numbers is partially decidable if the function \( f \) given by

\[
f(x) = \begin{cases} 1 & \text{if } M(x) \text{ holds,} \\ \text{undefined} & \text{if } M(x) \text{ does not hold,} \end{cases}
\]

is computable. (This function is called the partial characteristic function for \( M \).) If \( M \) is partially decidable, any algorithm for computing \( f \) is called a partial decision procedure for \( M \).

Note: In the literature the terms partially solvable, semi-computable, and recursively enumerable* are used with the same meaning as partially decidable.

6.2. Examples

1. The Halting problem (theorem 1.3) is partially decidable, since its partial characteristic function

\[
f(x, y) = \begin{cases} 1 & \text{if } P_x(y), \\ \text{undefined} & \text{otherwise,} \end{cases}
\]

is computable, by Church's thesis (or by observing that \( f(x, y) = 1(\psi_0(x, y)) \)).

2. Any decidable predicate is partially decidable: simply arrange for the decision procedure to enter a loop whenever it gives output 0.

3. For any computable function \( g(x) \) the problem '\( x \in \text{Dom}(g) \)' is partially decidable, since it has the computable partial characteristic function \( 1(g(x)) \). (Cf. corollary 1.2.)

4. The problem '\( x \in W_n \)' is not partially decidable: for if \( f \) is its partial characteristic function, then

\[
x \in \text{Dom}(f) \Rightarrow x \not\in W_n.
\]

Thus \( \text{Dom}(f) \) differs from the domain of every unary computable function: hence \( f \) is not computable.

* The reason for the use of this term will be explained in the next chapter.
We proceed to establish some of the important characteristics of partially decidable predicates. First we have the alternative characterisation that is given essentially in example 6.2(3) above.

6.3. Theorem

A predicate \( M(x) \) is partially decidable if and only if there is a computable function \( g(x) \) such that

\[
M(x) \iff x \in \text{Dom}(g).
\]

Proof. If \( M(x) \) is partially decidable with computable partial characteristic function \( f(x) \), then from the definition we have \( M(x) \iff x \in \text{Dom}(f) \). The converse is given by example 6.2(3) above. \( \square \)

The following characterisation of partially decidable predicates shows how they are related to decidable predicates.

6.4. Theorem

A predicate \( M(x) \) is partially decidable if and only if there is a decidable predicate \( R(x, y) \) such that

\[
M(x) \iff \exists y R(x, y).
\]

Proof. Suppose that \( R(x, y) \) is a decidable predicate and that \( M(x) \iff \exists y R(x, y) \). By corollary 2-5.3 the function \( g(x) = \mu y R(x, y) \) is computable; clearly

\[
M(x) \iff x \in \text{Dom}(g),
\]

so \( M(x) \) is partially decidable by theorem 6.3.

For the converse, suppose that \( M(x) \) is partially decidable, with partial decision procedure given by a program \( P \). Define a predicate \( R(x, y) \) by

\[
R(x, y) = P(x) \downarrow \text{in } y \text{ steps.}
\]

By corollary 5-1.3, \( R(x, y) \) is decidable. Moreover,

\[
M(x) \iff P(x) \downarrow \iff \exists y R(x, y)
\]

as required. \( \square \)

Note. From the appendix to chapter 5 it follows that the predicate \( R \) in this characterisation may be taken to be primitive recursive (see the note 1 following corollary 5-1.4).

The characterisation given by theorem 6.4 indicates an important way to think of partially decidable predicates. It shows that partial decision procedures can always be cast in the form of an unbounded search for a number \( y \) having some decidable property \( R(x, y) \). This search is most naturally carried out by examining successively \( y = 0, 1, 2, \ldots \) to find such a \( y \). The search halts if and when \( y \) is found such that \( R(x, y) \) holds; otherwise the search goes on forever.

We can use theorem 6.4 to establish some further properties of partially decidable predicates, that aid us in their recognition.

6.5. Theorem

If \( M(x, y) \) is partially decidable, then so is the predicate \( \exists y M(x, y) \).

Proof. Take a decidable predicate \( R(x, y, z) \) such that \( M(x, y) \iff \exists z R(x, y, z) \). Then we have

\[
\exists y M(x, y) \iff \exists z R(x, y, z).
\]

We can use the standard technique of coding the pair of numbers \( y, z \) by the single number \( u = 2^y 3^z \); then the search for a pair \( y, z \) such that \( R(x, y, z) \) reduces to the search for a single number \( u \) such that \( R(x, (u)_1, (u)_2) \), i.e.

\[
\exists y M(x, y) \iff \exists u R(x, (u)_1, (u)_2).
\]

The predicate \( S(x, u) = R(x, (u)_1, (u)_2) \) is decidable (by substitution) and so by theorem 6.4 \( \exists y M(x, y) \) is partially decidable. \( \square \)

Theorem 6.5 is described by saying that partially decidable predicates are closed under existential quantification. Its repeated application gives

6.6. Corollary

If \( M(x, y) \) is partially decidable, where \( y = (y_1, \ldots, y_m) \), then so is the predicate \( \exists y_1 \cdots \exists y_m M(x, y_1, \ldots, y_m) \).

Let us now consider some applications of the above results.

6.7. Examples

1. The following predicates are partially decidable.
   (a) \( x \in E_1 \) (n fixed). (The Printing problem: cf. theorem 1.6.)
   (b) \( W_1 \neq \emptyset \) (Cf. exercise 1.8(1)(g)).

Proofs
   (a) \( x \in E_1 \iff \exists z_1 \cdots \exists z_t \exists! P_0(z_1, \ldots, z_t) \downarrow \text{in } t \text{ steps} \).
   The predicate in the brackets on the right is decidable; apply corollary 6.6.
   (b) \( W_1 \neq \emptyset \iff \exists y \exists! P(y) \downarrow \text{in } t \text{ steps} \); again the predicate in brackets is decidable, so corollary 6.6 applies.
2. Provability in the predicate calculus is partially decidable (this is for those who have read § 5).

Proof. We proceed informally: in the predicate calculus a proof is defined as a finite object (usually a sequence of statements) in such a way that the predicate

\[ \text{Pr}(d, \sigma) \equiv \text{"d is a proof of the statement } \sigma \text{"} \]

is decidable. Then we have

\[ \sigma \text{ is provable } \Leftrightarrow \exists d \text{ Pr}(d, \sigma), \]

hence ‘\( \sigma \) is provable’ is partially decidable.

6.8. Diophantine predicates (cf. § 3)

Suppose that \( p(x_1, \ldots, x_n, y_1, \ldots, y_m) \) is a polynomial with integer coefficients. Then the predicate \( M(x) \) given by

\[ M(x) = \exists y_1 \ldots \exists y_m (p(x, y_1, \ldots, y_m) = 0) \]

is called a diophantine predicate, because of its obvious connection with diophantine equations. (The quantifiers \( \exists y_1, \ldots, \exists y_m \) are taken as ranging over \( \mathbb{N} \).)

Example. The predicate ‘\( x \) is a perfect square’ is diophantine, since it is equivalent to \( \exists y (x - y^2 = 0) \).

From corollary 6.6 we have immediately

6.9. Theorem

Diophantine predicates are partially decidable.

Proof. The predicate \( p(x, y) = 0 \) is decidable; apply corollary 6.6.

Clearly, diophantine predicates are partially decidable predicates that can be cast in a relatively simple form, and for a long time it was not known whether any undecidable diophantine predicates existed. This question is closely connected with Hilbert’s tenth problem (§ 3), as we shall see. It was a most remarkable achievement, therefore, when Matiyasevich proved in 1970:

6.10. Theorem

Every partially decidable predicate is diophantine.

The proof of this result by Matiyasevich rested heavily on earlier work of Davis, Robinson and Putnam, and is far too long to present here. Full proofs are given in Davis [1973], Bell & Machover [1977] and Manin [1977]. The major part of the proof consists in showing that diophantine predicates are closed under bounded universal quantification; i.e. if \( M(x, y) \) is diophantine then so is the predicate \( \forall y M(x, z) \). (It is an easy exercise to show that partially decidable predicates are closed under bounded universal quantification; see exercise 6.14(5) below.)

We can see how a negative solution to Hilbert’s tenth problem is easily derived from Matiyasevich’s theorem. First note that if the problem posed by Hilbert is decidable, then so is the problem of deciding for a general polynomial equation \( p(x_1, \ldots, x_n) = 0 \) (with integer coefficients) whether it has a solution in the natural numbers: this is because any natural number is expressible as the sum of four squares, so we simply look for integer solutions to

\[ p(x_1^2 + y_1^2 + z_1^2 + v_1^2, \ldots, x_n^2 + y_n^2 + z_n^2 + v_n^2) = 0. \]

Now take a polynomial \( p(x_1, \ldots, y_n) \) such that

\[ x \in W_n \iff \exists y_1 \ldots \exists y_m (p(x, y_1, \ldots, y_m) = 0) \]

(this is possible by Matiyasevich’s theorem). Then a decision procedure for Hilbert’s problem would give the following decision procedure for ‘\( x \in W_n \)’: to test whether \( a \in W_n \) see whether the polynomial \( q(y_1, \ldots, y_m) = p(a, y_1, \ldots, y_m) \) has a solution in \( \mathbb{N} \). So \( x \in W_n \) has been reduced to Hilbert’s problem; hence the latter is undecidable.

We shall mention another (surprising) consequence of Matiyasevich’s theorem in the next chapter.

We conclude this chapter with two important results, linking partially decidable predicates with decidable predicates (theorem 6.11) and computable functions (theorem 6.13).

6.11. Theorem

A predicate \( M(x) \) is decidable if and only if both \( M(x) \) and ‘not \( M(x) \)’ are partially decidable.

Proof. If \( M(x) \) is decidable, so is ‘not \( M(x) \)’, so both are partially decidable.

Conversely, suppose that partial decision procedures for \( M(x) \) and ‘not \( M(x) \)’ are given by programs \( F(x), G \). Then

\[ F(x) \downarrow \Leftrightarrow M(x) \text{ holds} \]

and

\[ G(x) \downarrow \Leftrightarrow \text{not } M(x) \text{ holds} \]

Moreover, for any \( x \), either \( F(x) \) or \( G(x) \), but not both. Thus the following is an algorithm for deciding \( M(x) \). Given \( x \), run the
computations $F(x)$ and $G(x)$ simultaneously (or carry out alternately one step in each computation), and go on until one of them stops. If it is $F(x)$ that stops, then conclude that $M(x)$ holds; if it is $G(x)$ that stops, then $M(x)$ does not hold.

This theorem gives an alternative proof that the predicate '$x \not\in W_1$' is not partially decidable. Similarly we have

6.12. Corollary
The predicate '$P_x(y) \uparrow$' (the Divergence problem; equivalently, '$y \not\in W_1$', or $\phi_x(y)$ is undefined) is not partially decidable.

Proof. If this problem were partially decidable, then by theorem 6.11 and example 6.2(1) the Halting problem $P_x(y)$ would be decidable. □

The final result of this chapter gives a useful way to show that a function is not computable.

6.13. Theorem
Let $f(x)$ be a partial function. Then $f$ is computable if and only if the predicate

$$f(x) = y$$

is partially decidable.

Proof. If $f$ is computable by a program $P$, then we have

$$f(x) = y \Leftrightarrow \exists! (P(x) \downarrow / y \text{ in } t \text{ steps}).$$

The predicate on the right is partially decidable by theorem 6.4 and corollary 5.1.3.

Conversely, suppose that the predicate '$f(x) = y$' is partially decidable. Let $R(x, y, t)$ be a decidable predicate such that $f(x) = y \Leftrightarrow \exists! R(x, y, t)$.

Then we have the following algorithm for computing $f(x)$.

Search for a pair of numbers $y, t$ such that $R(x, y, t)$ holds; if and when such a pair is found, then $f(x) = y$.

Hence $f$ is computable. (A formal proof of the computability of $f$ could be given by the standard technique of coding a pair $y, t$ by the single number $z = 2^3 t$. See exercise 6.14(8) below.) □

Further properties of partially decidable predicates are given in the exercises below (see in particular exercises 6.14(4, 5, 9)).

In the next chapter we will be studying unary partially decidable predicates in greater detail, in the guise of recursively enumerable sets. We shall see in particular why partially decidable predicates are often described as recursively enumerable predicates.

6.14. Exercises

1. Show that the following predicates are partially decidable:
   (a) '$E_2^n \neq \emptyset$' (n fixed),
   (b) '$\phi(x)$ is a perfect square',
   (c) '$n$ is a Fermat number'. (We say then $n$ is a Fermat number if there are numbers $x, y, z > 0$ such that $x^n + y^n = z^n$.)
   (d) 'There is a run of exactly $x$ consecutive $7$s in the decimal expansion of $\pi$'.

2. (For those knowing some group theory) Show that the word problem for any finitely presented group is partially decidable.

3. A finite set $S$ of $3 \times 3$ matrices is said to be mortal if there is a finite product of members of $S$ that equals the zero matrix. Show that the predicate '$S$ is mortal' is partially decidable. (It has been shown that this problem is not decidable; see Paterson [1970].)

4. Suppose that $M(x)$ and $N(x)$ are partially decidable; prove that the predicates '$M(x)$ and $N(x)$', '$M(x)$ or $N(x)$' are partially decidable. Show that the predicate 'not $M(x)$' is not necessarily partially decidable.

5. Suppose that $M(x, y)$ is partially decidable. Show that
   (a) '$\exists y < z : M(x, y)$' is partially decidable,
   (b) '$\forall y < z : M(x, y)$' is partially decidable.
   (Hint. If $f(x, y)$ is the partial characteristic function of $M$, consider the function $\prod_{y < z} f(x, y)$.)
   (c) '$\forall y M(x, y)$' is not necessarily partially decidable.

6. Show that the following predicates are diophantine.
   (a) '$x$ is even',
   (b) '$x$ divides $y$'.

7. (This exercise shows how the technique of reducibility (§ 1) may be used to show that a predicate is not partially decidable.)
   (a) Suppose that $M(x)$ is a predicate and $k$ a total computable function such that $x \in W_1$ iff $M(k(x))$ does not hold. Prove that $M(x)$ is not partially decidable.
   (b) Prove that '$\phi(x)$ is not total' is not partially decidable.
   (Hint. Consider the function $k$ in the proof of theorem 1.6.)
   (c) By considering the function

$$f(x, y) = \begin{cases} 1 & \text{if } P_x(x) \text{ does not converge in } y \text{ or fewier steps,} \\ \text{undefined} & \text{otherwise,} \end{cases}$$

Further properties of partially decidable predicates are given in the exercises below (see in particular exercises 6.14(4, 5, 9)).

In the next chapter we will be studying unary partially decidable predicates in greater detail, in the guise of recursively enumerable sets. We shall see in particular why partially decidable predicates are often described as recursively enumerable predicates.
show that 'φ₁ is total' is not partially decidable. (Hint: Use the s-m-r theorem and (a).)

8. Give a formal proof of the second half of Theorem 6.13, i.e. if 'f(x) = y' is partially decidable, then f is computable.

9. Suppose that $M(x_1, \ldots, x_n)$ is partially decidable and $g_1, \ldots, g_n$ are computable partial functions. Show that the predicate $N(y)$ given by

$$N(y) = M(g_1(y), \ldots, g_n(y))$$

is partially decidable. (We take this to mean that $N(y)$ does not hold if any one of $g_1(y), \ldots, g_n(y)$ is undefined.)

7

Recursive and recursively enumerable sets

The sets mentioned in the title to this chapter are subsets of \( \mathbb{N} \) corresponding to decidable and partially decidable predicates. We discuss recursive sets briefly in § 1. The major part of this chapter is devoted to the study of recursively enumerable sets, beginning in § 2; many of the basic properties of these sets are derived directly from the results about partially decidable predicates in the previous chapter. The central new result in § 2 is the characterisation of recursively enumerable sets that gives them their name: they are sets that can be enumerated by a recursive (or computable) function.

In §§ 3 and 4 we introduce creative sets and simple sets; these are special kinds of recursively enumerable sets that are in marked contrast to each other; they give a hint of the great variety existing within this class of sets.

1. Recursive sets

There is a close connection between unary predicates of natural numbers and subsets of \( \mathbb{N} \): corresponding to any predicate $M(x)$ we have the set \{ $x : M(x)$ holds\}, called the \textit{extent} of $M$ (which could, of course, be \( \emptyset \)); while to a set $A \subseteq \mathbb{N}$ there corresponds the predicate \( x \in A \). The name \textit{recursive} is given to sets corresponding in this way to predicates that are \textit{decidable}.

1.1. \textit{Definition}

Let $A$ be a subset of \( \mathbb{N} \). The \textit{characteristic function} of $A$ is the function $c_A$ given by

$$c_A(x) = \begin{cases} 1 & \text{if } x \in A, \\ 0 & \text{if } x \notin A. \end{cases}$$

\( ^1 \) As mentioned in a footnote to § 3 of the Prologue, predicates are often identified with their extent; that view would not be inconsistent with our exposition.
Then \( A \) is said to be \textit{recursive} if \( c_A \) is computable, or equivalently, if \( x \in A \) is a decidable predicate.

**Notes**
1. For obvious reasons, recursive sets are also called \textit{computable} sets.
2. If \( c_A \) is primitive recursive, the set \( A \) is said to be \textit{primitive recursive}.
3. The idea of a recursive set can be extended in the obvious way to subsets of \( \mathbb{N}^n \) (\( n > 1 \)), although in the text we shall (as is common practice) restrict the use of the term to subsets of \( \mathbb{N} \). There is no loss of generality in doing this, because recursive subsets of \( \mathbb{N} \) can easily be coded as recursive subsets of \( \mathbb{N} \).

### 1.2. Examples

1. The following sets are recursive.
   (a) \( \mathbb{N} \),
   (b) \( \mathbb{E} \) (the even numbers),
   (c) any finite set,
   (d) the set of prime numbers.

2. The following sets are \textit{not} recursive.
   (a) \( \{x : \phi_x \text{ is total} \} \) (theorem 5-2.1),
   (b) \( \{x : x \in W_x \} \) (theorem 6-1.1),
   (c) \( \{x : \phi_x = 0 \} \) (theorem 6-1.4).

The algebra of decidability (corollary 2-4.7) gives us the following properties of recursive sets immediately.

### 1.3. Theorem

If \( A, B \) are recursive sets, then so are the sets \( \bar{A}, A \cap B, A \cup B, A \setminus B \).

**Proof.** Direct translation of corollary 2-4.7.

Further facts about recursive sets will emerge in §2.

### 1.4. Exercises

1. Let \( A, B \) be subsets of \( \mathbb{N} \). Define sets \( A \oplus B \) and \( A \otimes B \) by
   \[
   A \oplus B = \{2x : x \in A\} \cup \{2x + 1 : x \in B\}
   \]
   \[
   A \otimes B = \{\pi(x, y) : x \in A \text{ and } y \in B\},
   \]
   where \( \pi \) is the pairing function \( \pi(x, y) = 2^x(2y + 1) - 1 \) of theorem 4-1.2. Prove that
   (a) \( A \oplus B \) is recursive iff \( A \) and \( B \) are both recursive,
   (b) If \( A, B \neq \emptyset \), then \( A \otimes B \) is recursive iff \( A \) and \( B \) are both recursive.

2. (a) Let \( B \leq \mathbb{N} \) and let \( n > 1 \); prove that if \( B \) is recursive then the predicate \( M(x_1, \ldots, x_n) \) given by
   \[
   M(x_1, \ldots, x_n) = 2^{x_1}3^{x_2} \cdot \ldots \cdot p_n^{x_n} \in B
   \]
   is decidable.
   (b) Let \( A \subseteq \mathbb{N}^n \); define \( A \) to be recursive if the predicate \( x \in A \) is decidable. Prove that \( A \) is recursive iff \( \{2^{x_1}3^{x_2} \cdot \ldots \cdot p_n^{x_n} : (x_1, \ldots, x_n) \in A\} \) is recursive.

### 2. Recursively enumerable sets

We turn now to the subsets of \( \mathbb{N} \) that correspond to partially decidable predicates. These constitute an important class, if only because of the many situations in which they occur.

#### 2.1. Definition

Let \( A \) be a subset of \( \mathbb{N} \). Then \( A \) is \textit{recursively enumerable} if the function \( f \) given by

\[
 f(x) = \begin{cases} 1 & \text{if } x \in A, \\ \text{undefined} & \text{if } x \notin A \end{cases}
\]

is computable (or, equivalently, if the predicate \( x \in A \) is partially decidable). The phrase recursively enumerable is almost universally abbreviated r.e.

**Notes**
1. The terms \textit{semi}-recursive sets and \textit{semi}-computable sets are also used to describe r.e. sets; indeed, from the above definition these names would appear more appropriate than \textit{recursively enumerable}. We will, nevertheless, adhere to the standard name recursively enumerable, which stems from the fact that these sets may also be defined as sets that can be enumerated by a recursive (or computable) function. This alternative characterization is given in theorem 2.7 below.

2. As with recursive sets, the idea of r.e. sets can be extended in the obvious way to subsets of \( \mathbb{N}^n \) (\( n > 1 \)), but there is no loss of generality in confining attention (as we do in the text) to r.e. subsets of \( \mathbb{N} \). See exercise 2.18(9) below.

#### 2.2. Examples

1. Let \( K = \{x : x \in W_x\} \); then \( K \) is an r.e. set that is not recursive. (example 6-6.2(1)). Its complement \( \overline{K} \) is not r.e. (example 6-6.2(4)).

2. Any recursive set is r.e. (example 6-6.2(2)).
3. The set \( \{ x : W_i \neq \emptyset \} \) is r.e. (example 6-6.7(1(b))).
4. If \( f \) is a computable function, then \( \text{Ran}(f) \) is r.e. (example 6-6.7(1a); cf. theorem 2.7 below).

Note. \( K \) is the standard notation for the set \( \{ x : x \in W_i \} \) (example 1 above), which plays a prominent role in the study of r.e. sets.

Most of the results for partially decidable predicates in chapter 6 § 6 translate immediately into the language of r.e. sets. We begin with

2.3. **Theorem**

A set is r.e. if and only if it is the domain of a unary computable function.

**Proof.** Theorem 6-6.3. \( \Box \)

We conclude from this theorem that the enumeration

\( W_0, W_1, W_2, \ldots \)

is an enumeration (with repetitions) of all r.e. sets. If \( A = W_n \), then \( n \) is called an index for \( A \).

From theorem 6-6.4 we obtain the next characterisation of r.e. sets.

2.4. **Theorem**

The set \( A \) is r.e. if and only if there is a decidable predicate \( R(x, y) \) such that

\[ x \in A \iff \exists y R(x, y). \]

(From the note following the proof of theorem 6-6.4 this predicate \( R \) may be taken to be primitive recursive.)

We also have the following immediately from theorem 6-6.5.

2.5. **Theorem**

Suppose that \( M(x, y, \ldots, y_n) \) is partially decidable; then the set \( \{ x : \exists y_1 \ldots \exists y_n M(x, y_1, \ldots, y_n) \} \) is r.e.

The following link between r.e. sets and recursive sets is an immediate application of theorem 6-6.11.

2.6. **Theorem**

The set \( A \) is recursive if and only if \( A \) and \( \bar{A} \) are r.e.

**Proof.** This is immediate from theorem 6-6.11, but it is instructive to give a formal proof of the non-trivial half of the proof. Suppose then that \( R \) and \( S \) are decidable predicates such that

\[ x \in A \iff \exists y R(x, y) \]
\[ x \in \bar{A} \iff \exists y S(x, y) \]

(we are using theorem 2.4). Now define a function \( f(x) \) by

\[ f(x) = \mu y (R(x, y) \lor S(x, y)) \]

By the results of chapter 2, \( f \) is computable; further, since for every \( x \), either \( x \in A \) or \( x \notin A \), \( f(x) \) is always defined, and we have

\[ x \in A \iff R(x, f(x)) \]

Thus \( x \in A \) is decidable, so \( A \) is recursive. \( \Box \)

We now turn to the characterisation of r.e. sets that gives them their name.

2.7. **Theorem**

Let \( A \subseteq \mathbb{N} \). Then the following are equivalent:

(a) \( A \) is r.e.,
(b) \( \bar{A} = \emptyset \) or \( A \) is the range of a unary total computable function,
(c) \( A \) is the range of a (partial) computable function.

**Proof.** We shall prove the chain of implications \( (a) \Rightarrow (b) \Rightarrow (c) \Rightarrow (a) \).

\( (a) \Rightarrow (b) \) Suppose that \( A \neq \emptyset \) and that \( A = \text{Dom}(f) \), where \( f \) is computed by a program \( P \). Choose an element \( a \in A \). Then \( A \) is the range of the following total binary function:

\[ g(x, t) = \begin{cases} x & \text{if } P(x \downarrow) \text{ in } t \text{ steps,} \\ a & \text{otherwise}. \end{cases} \]

Clearly \( g \) is computable. To complete the proof we construct a unary total computable function \( h \) having the same range as \( g \). Let

\[ h(z) = g(\langle z \rangle, \langle z \rangle). \]

Clearly \( \text{Ran}(h) = \text{Ran}(g) = A \).

\( (b) \Rightarrow (c) \) is trivial.

\( (c) \Rightarrow (a) \) Suppose that \( A = \text{Ran}(h) \) where \( h \) is an \( n \)-ary computable function. Then

\[ x \in A \iff \exists y_1 \ldots \exists y_n \forall y_{n+1} \exists y_{n+2} \cdots \exists y_{n+m} (h(y_1, \ldots, y_n) = x) \].

The predicate in brackets on the right is partially decidable (theorem 6-6.13) so applying theorem 2.5 we see that \( A \) is r.e. \( \Box \)
(The reader may have noticed that various parts of this theorem have been given, more or less explicitly, in examples and exercises earlier in this and other chapters.)

Notice that it is from theorem 2.7(b) particularly that the name recursively enumerable comes: a non-empty r.e. set is a set that can be enumerated as \( A = \{h(0), h(1), h(2), \ldots\} \) where \( h \) is a recursive (i.e. total computable) function. In fact, by using the results of chapter 5 (and appendix) it is easily seen that the enumerating function \( h \) in the proof of \((a) \Rightarrow (b)\) is primitive recursive.

Note also that theorem 2.7 tells us that the enumeration \( E_0, E_1, E_2, \ldots \) of the ranges of unary computable functions is another enumeration (with repetitions) of all r.e. sets. In informal terms, a set \( A \) is recursively enumerable if there is an informal effective procedure for compiling a list of the members of \( A \). Such a procedure would from time to time output a number to be added to the list. The procedure may go on \( \text{ad infinitum} \) (and certainly must if \( A \) is infinite). To see that a set \( A \) generated in this way is r.e., simply put

\[
f(0) = 1\text{st number listed by the procedure},
\]

\[
f(n) = (n + 1)\text{th number listed by the procedure},
\]

where \( f(n) \) is defined iff there is an \((n + 1)\)th number listed. Then clearly \( f \) is computable, and \( A = \text{Ran}(f) \) is r.e.

We can illustrate this with an example.

2.8. Example

The set \( \{x : \text{there is a run of exactly } x \text{ consecutive 7s in the decimal expansion of } \pi \} \) is r.e. (cf. exercise 6-6.14(1d)). The following is an informal procedure that generates this set of numbers: 'Run an algorithm that computes successive digits in the decimal expansion of \( \pi \). Each time a run of 7s appears, count the number of consecutive 7s in the run and add this number to the list.'

The characterisation of theorem 2.7 gives us a straightforward diagonal proof that total computable functions cannot be recursively enumerated.

2.9. Theorem

The set \( \{x : \phi_x \text{ is total} \} \) is not r.e.

Proof. (Cf. the suggested proof of this result given in exercise 6-6.14(7c).)

Suppose to the contrary that \( f \) is a total unary computable function that enumerates this set; i.e., \( \phi_{f(1)}, \phi_{f(2)}, \ldots \) is a list of all unary computable functions. Then we can easily make a diagonal construction of a total computable function \( g \) that differs from every function in this list. The diagonal motto says 'make \( g \) differ from \( \phi_{f(n)} \) at \( n \)', so we put

\[
g(x) = \phi_{f(x)}(x) + 1.
\]

Then \( g \) is computable and total, but \( g \neq \phi_{f(m)} \) for every \( m \). This is a contradiction. \( \square \)

There is one important result about partially decidable predicates that we have so far omitted to transfer to the setting of r.e. sets, namely the connection with diophantine predicates. First we make a definition.

2.10. Definition

A set \( A \subseteq \mathbb{N} \) is diophantine if there is a polynomial \( p(x_1, \ldots, y_n) \) with integer coefficients such that

\[
x \in A \iff \exists y_1 \ldots \exists y_n (p(x_1, y_1, \ldots, y_n) = 0).
\]

Of course, diophantine sets are r.e., and Matiyasevich's theorem (6-6.10) may be expressed (as it often is) as:

2.11. Theorem (Matiyasevich)

All r.e. sets are diophantine.

This is an appropriate place to mention a surprising (but easy) consequence of Matiyasevich's theorem.

2.12. Theorem

A set is r.e. if and only if it is the set of non-negative values taken by some polynomial \( p(x_1, \ldots, x_n) \) with integer coefficients (for values of \( x_1, \ldots, x_n \) from \( \mathbb{N} \)).

Proof. Suppose that \( A \) is the set of non-negative values taken by \( p(x_1, \ldots, x_n) \); then \( x \in A \iff \exists x_1 \ldots \exists x_n (p(x_1, \ldots, x_n) = x) \), so \( A \) is clearly r.e.

Conversely, if \( A \) is r.e. then by Matiyasevich's theorem there is a polynomial \( q(x_1, y_1, \ldots, y_n) \) such that

\[
x \in A \iff \exists y_1 \ldots \exists y_n (q(x, y_1, \ldots, y_n) = 0).
\]
Then consider the polynomial \( p(x, y) \) given by
\[
p(x, y) = x - (x + 1)(q(x, y))^2.
\]
p(x, y) is non-negative if, and only if, q(x, y) = 0, and then it takes the value x. Thus \( A \) is the set of non-negative values taken by \( p(x, y) \) as \( x, y, \ldots, y_n \) run through \( \mathbb{N} \).

(The restriction of \( x_1, \ldots, x_n \) to \( \mathbb{N} \) in the statement of this theorem is somewhat arbitrary; it is an easy exercise to see that the theorem is valid when \( x_1, \ldots, x_n \) are allowed to range over \( \mathbb{Z} \).)

One application of this result that has aroused considerable interest among mathematicians is to the set of prime numbers; this set, being r.e., is the set of positive values taken by a polynomial with integer coefficients, a result thought to be most unlikely before Matiyasevich came on the scene.

A refinement of theorem 2.12 shows that there is a single universal polynomial, which generates all r.e. sets; i.e., a polynomial \( p(z, x, y, \ldots, y_n) \) with the property that for any r.e. set \( A \) there is a number \( z \) such that
\[
x \in A \iff \exists y_1 \ldots \exists y_n (p(z, x, y_1, \ldots, y_n) = 0).
\]

To see this, simply note that the Halting problem \( 'x \in W_e' \) is diophantine and take \( z \) to be an index for \( A \).

At this stage we should summarise the various characterisations of r.e. sets that we now have available. The following are all equivalent conditions on a set \( A \) of natural numbers:

1. \( 'x \in A' \) is partially decidable (we have taken this as our basic definition),
2. \( A \) is the domain of a unary computable function; i.e., \( A = W_e \) for some \( e \) (theorem 2.3),
3. For some decidable predicate \( R(x, y) \), \( x \in A \iff \exists y R(x, y) \) (theorem 2.4),
4. For some partially decidable predicate \( M(x, y_1, \ldots, y_n) \), \( x \in A \iff \exists y_1 \ldots \exists y_n M(x, y_1, \ldots, y_n) \) (theorem 2.5),
5. If \( A \neq \emptyset \), \( A \) is the range of a total unary computable function (theorem 2.7),
6. \( A \) is the range of a computable function (theorem 2.7),
7. \( A \) is diophantine (theorem 2.11),
8. \( A \) is the set of non-negative values taken by a polynomial with integer coefficients (theorem 2.12).

Naturally, when working with r.e. sets one chooses the characterisation that is most convenient for the purpose in hand. We illustrate this in the proof of the next theorem.

2.13. Theorem
If \( A \) and \( B \) are r.e., then so are \( A \cap B \) and \( A \cup B \).

Proof. For \( A \cap B \) use characterisation (2). Suppose that \( A = \text{Dom}(f) \) and \( B = \text{Dom}(g) \) with \( f, g \) computable. Then \( A \cap B = \text{Dom}(fg) \), and \( fg \) is computable.

For \( A \cup B \) use characterisation (3). If \( A = \emptyset \) or \( B = \emptyset \) there is nothing to prove. So suppose that \( A = \text{Ran}(f) \) and \( B = \text{Ran}(g) \) where \( f, g \) are total computable. Define \( h \) by
\[
h(2x) = f(x),
\]
\[
h(2x + 1) = g(x).
\]

Then \( h \) is computable and clearly \( \text{Ran}(h) = A \cup B \).

(If it is instructive to find proofs for this theorem using each of the other characterisations of r.e. sets.)

Our next theorem gives another link between r.e. sets and recursive sets.

2.14. Theorem
An infinite set is recursive if and only if it is the range of a total increasing computable function, i.e., if it can be recursively enumerated in increasing order.

Proof. Suppose that \( A \) is recursive and infinite; then \( A \) is enumerated by the increasing function \( f \) given by
\[
f(0) = \mu y (y \in A),
\]
\[
f(n + 1) = \mu y (y \in A \text{ and } y > f(n)).
\]
Moreover, \( f \) is computable by minimalisation, recursion and the recursiveness of \( A \).

Conversely, suppose that \( A \) is the range of the computable total increasing function \( f \), i.e., \( f(0) < f(1) < f(2) < \ldots \). It is clear that if \( y = f(n) \) then \( n \leq y \). Hence we have
\[
y \in A \iff y \in \text{Ran}(f)
\]
\[
\iff \exists n \leq y (f(n) = y)
\]
and the predicate on the right is decidable. Hence \( A \) is recursive.
(An alternative proof could be given by showing that $A$ is r.e.; we leave this as an exercise for the reader.)

The above theorem may be applied to prove

2.15. **Theorem**

Every infinite r.e. set has an infinite recursive subset.

**Proof.** Let $A = \text{Ran}(f)$ where $f$ is a total computable function. We can effectively enumerate a subset of $A$ in increasing order by a function $g$ as follows

\[
g(0) = f(0), \quad g(n + 1) = f(x), \text{ where } x = \mu y (f(y) > g(n)).
\]

Since $A = \text{Ran}(f)$ is infinite, $g$ is totally defined. By construction, $\text{Ran}(g) \subseteq \text{Ran}(f)$ and $g$ is increasing. It is clear that $g$ is computable, by minimisation and recursion. Hence by theorem 2.14, $\text{Ran}(g)$ is an infinite recursive subset of $A$. □

We conclude this section with a theorem of Rice and Shapiro about r.e. sets of indices. We shall need this result in chapter 10, and there are other applications we can make immediately, but it is of significance in its own right. The theorem and its proof are generalisations of Rice's theorem (5-1.7). (In the statement of this theorem, by a finite function we mean a function whose domain is finite; note that all finite functions are computable.)

2.16. **Theorem** (Rice–Shapiro)

Suppose that $\mathcal{A}$ is a set of unary computable functions such that the set $\{x : \phi_x \in \mathcal{A}\}$ is r.e. Then for any unary computable function $f$,

\[
f \in \mathcal{A} \text{ iff } \text{there is a finite function } \theta \leq f \text{ with } \theta \in \mathcal{A}.
\]

Before we prove this result, let us illustrate how it can be used to give quick proofs of non-recursive enumerability. (Further applications of this kind are given in exercises 2.18 below.)

2.17. **Corollary**

The sets $\{x : \phi_x \text{ is total}\}$ and $\{x : \phi_x \text{ is not total}\}$ are not r.e.

**Proof.** For $A = \{x : \phi_x \text{ is total}\}$ we apply the Rice–Shapiro theorem to the set $\mathcal{A} = \{f : f \in \mathcal{E}_1 \text{ and } f \text{ is total}\}$. For no $f \in \mathcal{A}$ is there a finite $\theta \leq f$ with $\theta \in \mathcal{A}$. Hence $A$ is not r.e.

For $B = \{x : \phi_x \text{ is not total}\}$, consider the set $\mathcal{B} = \{f : f \in \mathcal{E}_1 \text{ and } f \text{ is not total}\}$. Then if $f$ is any total computable function, $f \notin \mathcal{B}$; but every finite function $\theta \leq f$ is in $\mathcal{B}$. So $B$ cannot be r.e., by the Rice–Shapiro theorem. □

(Note. This is the third proof we have of the non-recursive enumerability of the indices of total functions; others are exercise 6.6.14(7c) and theorem 2.9 above. The reader will see that the proof suggested in the first of these is actually the specialisation of the following proof.)

We return to the proof of the Rice–Shapiro theorem.

**Proof of theorem 2.16**

Let $A = \{x : \phi_x \in \mathcal{A}\}$. We are given that $A$ is r.e. We shall show that if either implication in the statement of the theorem is false, then the problem ‘$x \in K$’ can be reduced to ‘$x \in A$’. (Recall from example 2.2(1) that $K = \{x : x \in W_x\}$.) This would show that $K$ is r.e., a contradiction.

Suppose first that $f \in \mathcal{A}$ but $\theta \notin \mathcal{A}$ for all finite $\theta \leq f$. Let $P$ be a program such that $P(z,t) = \begin{cases} f(t) & \text{if } P(z) \text{ is in } t \text{ or fewer steps}, \\ \text{undefined} & \text{if } P(z) \text{ is not in } t \text{ or fewer steps}. \end{cases}$

The $\sim - m - n$ theorem provides a total computable function $s(z)$ such that $g(z,t) = \phi_{s(z)}(t)$. Note that by construction $\phi_{s(z)} \in \mathcal{A}$ for all $z$. We claim further that

\[
(\ast) \quad \begin{cases} z \in K \Rightarrow \phi_{s(z)} \text{ is finite } \text{(hence } \phi_{s(z)} \notin \mathcal{A}), \\ z \notin K \Rightarrow \phi_{s(z)} = f \text{ (hence } \phi_{s(z)} \in \mathcal{A}). \end{cases}
\]

Now $(\ast)$ means that $z \in K \Rightarrow s(z) \in A$, which implies that $K$ is r.e., a contradiction. Hence there must be a finite $\theta \leq f$ with $\theta \in \mathcal{A}$.

For the reverse implication, suppose that $f$ is a computable function, such that there is a finite function $\theta \in \mathcal{A}$ with $\theta \leq f$, but $f \notin \mathcal{A}$. Define a computable function $g(z,t)$ by

\[
g(z,t) = \begin{cases} f(t) & \text{if } t \in \text{Dom}(\theta) \text{ or } z \in K, \\ \text{undefined} & \text{otherwise}. \end{cases}
\]

The $\sim - m - n$ theorem provides a total computable $s(z)$ such that $g(z,t) = \phi_{s(z)}(t)$. From the definition of $g$ and the fact that $\theta \leq f$ we see that $z \in K \Rightarrow \phi_{s(z)} = f$ (hence $\phi_{s(z)} \in \mathcal{A}$).
and 

\[ z \in K \Rightarrow \phi_{s(z)} = f|\text{Dom}(\theta) = \theta \] 

(hence \( \phi_{s(z)} \in \mathcal{A} \)).

But this means that \( z \in K \Rightarrow s(z) \in A \), again showing that \( K \) is r.e., a contradiction. Thus \( f \in \mathcal{A} \) as required. \( \square \)

We leave it as an exercise for the reader to see how the Rice–Shapiro theorem generalises Rice’s theorem (exercise 2.18(12) below).

2.18. **Exercises**

1. For any \( a \in \mathbb{N} \), let \( W_a = \{ x : \phi_a(x) = a \} \). Show that \( W_a \) is r.e. (all \( a \)). Does the enumeration \( W_0, W_1, W_2 \ldots \) include all r.e. sets?

2. Show that the set \( \{ x : \phi_x \) is not injective\} is r.e.

3. Show that there are total computable functions \( k, l \) such that for every \( x \), \( W_x \in \mathcal{E}_{k(x)} \) and \( E_x = W_{l(x)} \).

4. Suppose that \( A \) is an r.e. set. Show that the sets \( \bigcup_{x \in A} W_x \) and \( \bigcup_{x \in \overline{A}} E_x \) are both r.e.

5. Let \( f \) be a unary computable function, and suppose that \( A \subseteq \text{Dom}(f) \), and let \( g = f|A \). Prove that \( g \) is computable iff \( A \) is r.e.

6. Let \( f \) be a unary function. Prove that \( f \) is computable iff the set \( \{ x : 2^x \in \text{Dom}(f) \} \) is r.e.

7. (Cf. theorem 2.14.) Let \( A \) be an infinite r.e. set. Show that \( A \) can be enumerated without repetitions by a total computable function.

8. Which of the following sets are r.e.? Which are r.e.? Which have r.e. complement?

   a. \( \{ x : x \in E_x \} \)

   b. \( \{ x : x \) is a perfect square\}.

   c. \( \{ x : \phi_x \) is injective\}.

   d. \( \{ x : \) there is a run of at least \( x \) consecutive 7s in the decimal expansion of \( \pi \} \)

   e. \( \{ x : P_m(x) \) \) (\( m \) is fixed).

9. (Cf. Exercise 1.4(21)) (a) Let \( B \subseteq \mathbb{N} \) and let \( n > 1 \); prove that if \( B \) is r.e. then the predicate \( M(x_1, \ldots, x_n) \) given by \( M(x_1, \ldots, x_n) = 2^{x_1}3^{x_2}\ldots p_n^{x_n} \in B \) is partially decidable.

(b) Let \( A \subseteq \mathbb{N} \), define \( A \) to be r.e. if the predicate \( \{ x \in A \} \) is partially decidable. Prove that \( A \) is r.e. iff \( (2^{x_1}3^{x_2}\ldots p_n^{x_n} : (x_1, \ldots, x_n) \in A) \) is r.e.

(c) Prove that \( A \subseteq \mathbb{N} \) is r.e. iff \( A = \emptyset \) or there is a total computable function \( f : \mathbb{N} \to \mathbb{N} \) such that \( A = \text{Ran}(f) \). (By a computable function \( f \) from \( \mathbb{N} \) to \( \mathbb{N} \) we mean an \( n \)-tuple \( f = (f_1, \ldots, f_n) \) where each \( f_i \) is a unary computable function and \( f(x) = (f_1(x), \ldots, f_n(x)) \).)

10. Suppose that \( f \) is a total computable function, \( A \) a recursive set and \( B \) an r.e. set. Show that \( f^{-1}(A) \) is recursive and that \( f(A), f(B) \) and \( f^{-1}(B) \) are r.e. but not necessarily recursive. What extra information about these sets can be obtained if \( f \) is a bijection?

11. Use the Rice–Shapiro theorem to show that the following problems are not partially decidable: (a) \( \{ x : W_x = \emptyset \} \), (b) \( \{ x : W_x \) is finite\}, (c) \( \{ x : W_x \) is infinite\}, (d) \( \{ x : \phi_x \) is 0\}, (e) \( \{ x : \phi_x \neq 0 \} \).

12. Prove Rice’s theorem (theorem 6.1.7) from the Rice–Shapiro theorem (theorem 2.16). (Hint: Suppose that \( \phi_e \in \mathcal{B} \) is decidable; then both \( \mathcal{B} \) and \( \mathcal{C} \setminus \mathcal{B} \) satisfy the conditions of Rice–Shapiro; consider the cases \( f \in \mathcal{B} \) and \( f \notin \mathcal{B} \).)

13. (a) Let \( K_0 = \{ x : \phi_0(x) = 0 \} \) and \( K_1 = \{ x : \phi_1(x) = 1 \} \). Show that \( K_0 \) and \( K_1 \) are r.e. and that they are recursively inseparable, i.e., \( K_0 \cap K_1 = \emptyset \) and there is no recursive set \( C \) such that \( K_0 \subseteq C \) and \( K_1 \subseteq \overline{C} \), in particular neither \( K_0 \) nor \( K_1 \) is recursive. (Hint: Suppose that there is such a set \( C \) and let \( m \) be an index for its characteristic function; consider whether or not \( m \in C \).) (b) Show that two disjoint sets \( A, B \) are recursively inseparable (in the above sense) iff whenever \( A \subseteq W_m, B \subseteq W_{m+1} \) and \( W_m \cap W_{m+1} = \emptyset \), then there is a number \( x \notin W_m \cup W_{m+1} \). (Note. Recursive inseparability for a pair of disjoint sets corresponds to non-recursiveness for a single set; pairs of recursively inseparable sets that are also r.e. correspond to r.e. sets that are not recursive.)

3. **Productive and creative sets**

Our chief concern in this section is to discuss a special class of r.e. sets called creative sets. These are r.e. sets whose complement fails to be r.e. in a rather strong way. Thus we begin by considering a class of non-r.e. sets, among whose complements creative sets are to be found.

Suppose that \( A \) is any set that is not r.e.; then if \( W_x \) is an r.e. set contained in \( A \), there must be a number \( y \in A \backslash W_x \). This number \( y \) is a witness to the fact that \( A \neq W_x \). It turns out that for some non-r.e. sets it is
possible to find such a witness in an effective way. Consider, for example, the non-r.e. set $K = \{x : x \notin W_x\}$. If $W_e \subseteq K$, we cannot have $x \in W_x$ (for then $x \in K$, so $W_x \notin K$); hence $x \in K \setminus W_x$. So $x$ itself is a witness that $W_e \notin K$.

The name productive is used to describe non-r.e. sets for which a witness can always be computed in this way.

3.1. Definition

A set $A$ is productive if there is a total computable function $g$ such that whenever $W_e \subseteq A$, then $g(x) \in A \setminus W_e$. The function $g$ is called a productive function for $A$. This is illustrated by fig. 7a.

Example. The set $K$ is productive, with productive function $g(x) = x$.

Many examples of productive sets are obtained from the following theorem, which incorporates the idea of reducibility that was discussed in the previous chapter.

3.2. Theorem

Suppose that $A$ and $B$ are sets such that $A$ is productive, and there is a total computable function $f$ such that $x \in A$ iff $f(x) \in B$. Then $B$ is productive.

Proof. Let $g$ be a productive function for $A$. Suppose that $W_e \subseteq B$. Then $f^{-1}(W_e) \subseteq f^{-1}(B) = A$; moreover, $f^{-1}(W_e)$ is r.e., so there is $z$ such that $f^{-1}(W_e) = W_z$. Now $W_z \subseteq A$, and so $g(z) \in A \setminus W_z$, from which we see that $f(g(z)) \in B \setminus W_z$, i.e., $f(g(z))$ is a witness to the fact that $W_z \notin B$ (fig. 7b).

We now need to obtain the witness $f(g(z))$ effectively from $x$. A simple application of the s-m-n theorem provides a total computable function $k(x)$ such that $W_{k(x)} = f^{-1}(W_x)$ (apply the s-m-n theorem to the function $\phi_x(f(y))$). Then putting $z = k(x)$ we see from the above reasoning that if $W_e \subseteq B$ then $f(g(k(x))) \in B \setminus W_e$. Hence $B$ is productive, with productive function $f(g(k(x)))$. □

3.3. Examples

The following sets are productive:

(a) $\{x : \phi_x \neq \emptyset\}$,
(b) $\{x : c \in W_x\}$ (c a fixed number),
(c) $\{x : c \in E_x\}$ (c a fixed number).

(For each of these sets apply theorem 3.2 using $K$ and the functions obtained in theorem 6-1.4 (for (a)) and theorem 6-1.6 (for (b) and (c)).

The above examples of productive sets and many more may be obtained from the following general application of theorem 3.2, based on our proof of Rice's theorem.

3.4. Theorem

Suppose that $B$ is a set of unary computable functions with $f \in B$ and $B = \emptyset$. Then the set $B = \{x : \phi_x \in B\}$ is productive.

Proof. Choose a computable function $g \in B$. Proceeding exactly as in the proof of Rice's theorem (6-1.7) obtain a total computable function
The examples 3.7(a), (b) could be obtained by immediate application of this theorem, similarly we have:

3.9. Example
The set \( A = \{ x : W_x \neq \emptyset \} \) is creative; this set is obviously r.e. and corresponds to the set \( A = \{ f \in \mathcal{C} : f \neq f_0 \} \).

Many of the exercises at the end of the section may be done with the aid of theorem 3.8.

All examples of non-recursive r.e. sets that we have encountered so far are creative. (The reader might care to prove this for the examples that we have not dealt with explicitly.) The question then arises as to whether all non-recursive r.e. sets are creative. The idea that this might be the case is reinforced by theorem 3.8, and further examples in the exercises below. It turns out, however, that this conjecture is false: by a special construction we can obtain r.e. sets that are neither recursive nor creative. Section 4 will be devoted to that task.

The construction to be made in the next section is inspired by theorem 3.11 below, which will show that a productive set (and hence the complement of a creative set), although not itself r.e., does contain an infinite r.e. subset. (The secret of constructing an r.e. set \( A \) that is neither recursive nor creative will be to ensure that \( A \) does not have this property.)

The proof of the theorem will be facilitated by first isolating the following technical result.

3.10. Lemma
Suppose that \( g \) is a total computable function. Then there is a total computable function \( k \) such that for all \( x \), \( W_{k(x)} = W_x \cup \{ g(x) \} \).

Proof: Using the \( s-m-n \) theorem, take \( k(x) \) to be a total computable function such that

\[
\phi_{k(x)}(y) = \begin{cases} 1 & \text{if } y \in W_x \text{ or } y = g(x), \\ \text{undefined} & \text{otherwise.} \end{cases}
\]

3.11. Theorem
A productive set contains an infinite r.e. subset.

Proof: Let \( A \) be a productive set with productive function \( g \). The idea is to enumerate without repetition an infinite set \( B = \{ y_0, y_1, \ldots \} \subseteq A \) in the following way.
(1) Take \( e_0 \) such that \( W_{e_0} = \emptyset \); since \( W_{e_0} \subseteq A \), then \( g(e_0) \in A \). Put \( y_0 = g(e_0) \).

(2) For \( n \geq 0 \), suppose that \( y_0, \ldots, y_n \) have been given so that \( \{y_0, \ldots, y_n\} \subseteq A \). Find an index \( e_{n+1} \) such that \( \{y_0, \ldots, y_n\} \subseteq W_{e_{n+1}} \). Then \( g(e_{n+1}) \in A \setminus W_{e_{n+1}} \); thus if we put \( y_{n+1} = g(e_{n+1}) \) we have \( y_{n+1} \in A \) and \( y_{n+1} \neq y_0, \ldots, y_n \) (see fig. 7c).

To see that this enumeration of \( y_0, y_1, \ldots \) is an effective one, we use lemma 3.10. From the above discussion, when looking for the index \( e_{n+1} \) we require that

\[
W_{e_{n+1}} = W_{e_n} \cup \{y_n\} = W_{e_n} \cup \{g(e_n)\}
\]

(\( k \) is the function given by lemma 3.10). Thus we may define \( e_{n+1} \) to be \( k(e_n) \); then the sequence \( e_0, e_1, \ldots \) is given by the recursion equations

\[
e_{n+1} = k(e_n)
\]

and is hence computable. Now \( y_n = g(e_n) \), so the sequence \( y_0, y_1, \ldots \) is also computable. Thus \( B = \{y_0, y_1, \ldots\} \), being the range of a computable function, is r.e. By construction, \( B \subseteq A \) and \( B \) is infinite. \( \square \)

For the record, we state the obvious

3.12. Corollary
If \( A \) is creative, then \( \overline{A} \) contains an infinite r.e. subset.

3.13. Exercises
1. Show that the following sets are productive:
   \( x : W_x \) is finite.

Fig. 7c: Enumerating an infinite subset of \( A \) (theorem 3.11).

(\( x : \phi_x \) is not surjective),
(\( x : \phi_x \) is injective),
(\( x : \phi_x \) is not a polynomial function).

2. Prove that the following sets are creative:
   \( x : x \in E_x \),
   \( x : x \in E_x^{\omega} \setminus \emptyset \) (\( n \) fixed),
   \( x : \phi_x \) is not injective,
   \( \{x : \phi_x(x) \in A\}, \) where \( A \) is any non-empty r.e. set.
   \( x : \phi_x(x) = f(x) \), where \( f \) is any total computable function.

3. Prove that if \( B \) is r.e. and \( A \cap B \) is productive, then \( A \) is productive.

4. Prove that if \( C \) is creative and \( A \subseteq C = \emptyset \), then \( C \cap A \) is creative.

5. Prove that every productive set contains an infinite recursive subset.

6. For any sets \( A, B \) define the sets \( A \oplus B \) and \( A \otimes B \) as in exercise 1.4(1). Suppose that \( B \) is r.e. Show that \( (a) \) if \( A \) is creative, then so are \( A \oplus B \) and \( A \otimes B \) (provided \( B \neq \emptyset \)),
   \( b \) if \( B \) is recursive, then the implications in \( (a) \) reverse.

7. Let \( \mathcal{B} \) be a set of unary computable functions, and suppose that
   \( g \in \mathcal{B} \) is such that for all finite \( \theta \subseteq g, \theta \in \mathcal{B} \). Prove that the set
   \( \{x : \phi_x \in \mathcal{B}\} \) is productive.
   (Hint. Follow the first part of the proof of the Rice-Shapiro theorem.)

8. Use the result of question 7 to show that the following sets are productive:
   \( x : \phi_x \) is total,
   \( x : \phi_x \) is a polynomial function.

9. (Cf. exercise 2.18(13)) Disjoint sets \( A, B \) are said to be effectively recursively inseparable if there is a total computable function \( f \) such that whenever \( A \subseteq W_a, B \subseteq W_b \) and \( W_a \cap W_b = \emptyset \), then \( f(a, b) \in W_a \cup W_b \) (see fig. 7d).
   \( a \) Prove that the sets \( K_0 = \{x : \phi_x(x) = 0\} \) and \( K_1 = \{x : \phi_x(x) = 1\} \) are effectively recursively inseparable.
   (Hint. Find a total computable function \( f \) such that if \( W_a \cap W_b = \emptyset \), then
   \[
   \phi_{\overline{f(a,b)}}(x) =
   \begin{cases}
   1 & \text{if } x \in W_a \\
   0 & \text{if } x \in W_b \\
   \text{undefined} & \text{otherwise}
   \end{cases}
   \]
   \( b \) Prove that \( (a) \) if \( A \) is creative, then so are \( A \oplus B \) and \( A \otimes B \) (provided \( B \neq \emptyset \)),
   \( b \) if \( B \) is recursive, then the implications in \( (a) \) reverse.

(\( x : \phi_x \) is not surjective),
(\( x : \phi_x \) is injective),
(\( x : \phi_x \) is not a polynomial function).
Fig. 7d. Effectively recursively inseparable sets (exercise 3.13(9)).

(b) Suppose that $A$, $B$ are effectively recursively inseparable. Prove that if $A$, $B$ are both r.e. then they are both creative.

(Note. Extending the idea of effectiveness to a pair of recursively inseparable sets in this way parallels the step from a non-r.e. set to a set with productive complement; the counterpart to a single creative set is then a pair of effectively recursively inseparable sets that are both r.e.)

4. Simple sets

Our task in this section is to show that there are sets satisfying the following definition and hence (in view of theorem 4.2 below) to establish that not all non-r.e. sets are creative.

4.1. Definition

A set $A$ is simple if

(a) $A$ is r.e.,
(b) $A$ is infinite,
(c) $A$ contains no infinite r.e. subset.

The idea in (b), (c) of this definition is to pinpoint some features of a set that are not possessed by any recursive or creative set. Thus, although as yet we have no examples of simple sets, we can easily see that

4.2. Theorem

A simple set is neither recursive nor creative.

Proof. Suppose that $A$ is a simple set. From (b) and (c) of the definition, $A$ is not r.e., so $A$ is not recursive. By theorem 3.11 and (c) of the definition, $A$ is not creative. □

The following construction of a simple set is due to Post.

4.3. Theorem

There is a simple set.

Proof. We shall define a computable partial function $f$ such that the range of $f$ contains at least one member from every infinite r.e. set. This is done by arranging that if $\phi_i$ is total and $E_i$ is infinite, then $f(x) \in E_i$. To make $\text{Ran}(f)$ simple we must at the same time ensure that $\text{Ran}(f)$ is infinite. We shall see that both conditions are met by the function $f$ defined informally as follows:

To compute $f(x)$: compute $\phi_{i_1}(0), \phi_{i_1}(1), \ldots$ in succession (do not proceed to the computation of $\phi_{i_1}(y+1)$ unless and until $\phi_{i_1}(y)$ has been computed); stop if and only if a number $z$ is found such that $\phi_{i_1}(z) > 2x$; in that case put $f(x) = \phi_{i_1}(z)$. (Formally we have $f(x) = \phi_{i_1}(\mu z (\phi_{i_1}(z) > 2x))$, demonstrating clearly that $f$ is computable.)

Put $A = \text{Ran}(f)$; then $A$ is r.e. We now verify that $A$ is simple.

Suppose that $B$ is any infinite r.e. set. Then there is a total computable function $\phi_0$ such that $B = E_0$. Since $B$ is infinite, the construction ensures that $f(b)$ is defined and $f(b) \in E_0 = B$. Hence $B \subseteq A$.

To see that $A$ is infinite, note that if $f(x)$ is defined, then $f(x) > 2x$. Thus, for any $n$, the members of $A$ that are in the set $\{0, 1, 2, \ldots, 2n\}$ are among $f(0), \ldots, f(n-1)$. This means that $A$ contains more than $n$ elements, for any $n$. Hence $A$ is infinite. □

The construction of a simple set is but the first and one of the easiest of a wide variety of constructions that yield r.e. sets with all kinds of special properties. These are beyond the scope of this book; the interested reader should consult a text such as Rogers [1967], where he will find r.e. sets rejoining in names such a hypersimple, hyperhypersimple, pseudocreative, and maximal. (See also exercise 4.4(3) below for an example of an r.e. set that is neither recursive, creative nor simple.)

4.4. Exercises

1. Suppose that $A$ and $B$ are simple sets. Show that the set $A \oplus B$ is simple. (For the definition of $\oplus$ see exercise 1.4(1)).
2. Suppose that $f$ is a total injective computable function such that \( \text{Ran}(f) \) is not recursive. (Exercise 2.18(7) showed that such functions abound.) Show that the set \\
\[ A = \{ x : \exists y (y > x \text{ and } f(y) < f(x)) \} \]

is simple. (Hint. To see that $A$ is infinite, assume the contrary and show that there would then be a sequence of numbers $y_0 < y_1 < y_2 < \ldots$ such that $f(y_0) > f(y_1) > f(y_2) > \ldots$. To see that $A$ does not contain an infinite r.e. set $B$, suppose to the contrary that $B \subseteq A$. Then show that the problem $z \in \text{Ran}(f)$ is decidable as follows. Given $z$, find $n \in B$ such that $f(n) > z$; now use the fact that $n \notin A$ to devise a finite procedure for testing whether $z \in \text{Ran}(f)$.)

3. Show that if $A$ is simple, then $A \bigcirc N$ is r.e., but neither recursive, creative nor simple (see exercise 3.13(6)).

4. Let $A$, $B$ be simple sets. Prove that $A \bigcirc B$ is not simple but that $A \bigcirc B$ is simple.

8

Arithmetic and Gödel's incompleteness theorem

The celebrated incompleteness theorem of Gödel [1931] is one of many results about formal arithmetic that involve an interplay between computability and logic. Although full proofs in this area are beyond the scope of this book, we are able to outline some of the arguments discovered by Gödel and others. We shall highlight particularly the part played by computability theory, which in many cases can be viewed as an application of the phenomenon of creative and productive sets.

In §§ 1 and 2 we present some results about formal arithmetic that lead up to the full Gödel incompleteness theorem in § 3. In the final section the question of undecidability in formal arithmetic, already touched upon in § 2, is taken up again. Our presentation in this chapter does not assume any knowledge of formal logic.

1. Formal arithmetic

The formalisation of arithmetic begins by specifying a formal logical language $L$ that is adequate for making statements of ordinary arithmetic of the natural numbers. The language $L$ has its own alphabet, which includes the symbols $0$, $1$, $+$, $\times$, $=$ (having the obvious meanings), and also symbols for logical notions as follows: $\neg$ ('not'), $\land$ ('and'), $\lor$ ('or'), $\rightarrow$ ('implies'), $\forall$ ('for all'), $\exists$ ('there exists'). (In this chapter we will reserve the symbols $\forall$, $\exists$ for use in $L$, and write the phrase 'for all' and 'there exists' when needed in informal contexts.) In addition, $L$ has symbols $x$, $y$, $z$, \ldots for variables, and brackets ( and ), and there may be other symbols besides.

The statements (or formulas) of $L$ are defined to be the meaningful finite sequences of symbols from the alphabet of $L$. For instance, the statement

\[ \exists y (y \times (1 + 1) = x) \]

is the formal counterpart of the informal statement 'x is even'. It is helpful
to abbreviate the expression $1 + 1$ by $2$, $(1 + 1) + 1$ by $3$, and so on for all natural numbers. Then the false informal statement '5 is even' would be expressed formally in $L$ by the statement

$$\exists y (y \times 2 = 5).$$

We can similarly express in $L$ formal counterparts of many informal statements of ordinary arithmetic: for 'x > y' we would write

$$\exists z (z = 0) \land (y + z = x).$$

(The statement $\neg (z = 0)$ is often abbreviated by $z \neq 0$.) For 'x is prime' we would write

$$(x \neq 0) \land (x \neq 1) \land \forall y \forall z (x = y \times z \rightarrow (y = 1 \lor z = 1)).$$

Let us denote by $\mathcal{F}$ the set of all possible meaningful statements of the language $L$. Then $\mathcal{F}$ divides into two important sets, namely

$\mathcal{F}_t$ = the set of all statements that are true in the ordinary arithmetic of $\mathbb{N}$,

$\mathcal{F}_f$ = the set of all statements that are false in the ordinary arithmetic of $\mathbb{N}$.

Mathematicians would like to discover as much as possible about the set $\mathcal{F}$. A natural question from the point of view of computability is

(1.1)(a) Is $\mathcal{F}$ recursive, or even recursively enumerable?

Another question, important for the mathematician and philosopher alike is

(1.1)(b) Is there a simple-minded subset of $\mathcal{F}$ (a set of axioms) from which all other statements in $\mathcal{F}$ can be proved?

We shall discover that the answer to both of these questions is no.

Question 1.1(a) above can be made precise by means of a standard coding procedure. It is quite routine to specify an effective enumeration of the set $\mathcal{F}$, without repetitions, using a procedure similar to that used to enumerate programs in chapter 4. Let us assume that this has been done, and let us denote by $\theta_n$ the $(n + 1)$-th statement of $\mathcal{F}$ in this enumeration, so that

$$\mathcal{F} = \{ \theta_0, \theta_1, \theta_2, \ldots \}.$$ 

The effectiveness of this enumeration means that given $n$ we can effectively find and write down the statement $\theta_n$, and conversely, given any statement $\sigma$ in $\mathcal{F}$ we can effectively compute the code number $n$ such that $\sigma = \theta_n$.

This coding of statements is now used to code any set of statements $\mathcal{S}$ by the set of numbers

$$X = \{ n : \theta_n \in \mathcal{S} \}.$$ 

We say that $\mathcal{S}$ is recursive if $X$ is recursive.

We say that $\mathcal{S}$ is productive if $X$ is productive.

We say that $\mathcal{S}$ is creative if $X$ is creative.

This gives the question 1.1(a) above a precise meaning.

One of the key results that makes computability an extremely useful tool when investigating formal arithmetic is the following, due to Gödel: we present it without any proof.

1.2. Lemma

Suppose that $M(x_1, \ldots, x_n)$ is a decidable predicate. Then it is possible to construct a statement $\sigma(x_1, \ldots, x_n)$ of $L$ that is a formal counterpart of $M(x_1, \ldots, x_n)$ in the following sense: for any $a_1, \ldots, a_n \in \mathbb{N}$

$$M(a_1, \ldots, a_n) \text{ holds iff } \sigma(a_1, \ldots, a_n) \in \mathcal{F}.$$ 

Consider now the creative set $K$. By theorem 7.2-4 there is a decidable predicate $R(x, y)$ such that

$$x \in K \iff \text{there is } y \text{ such that } R(x, y).$$ 

Applying lemma 1.2 to the predicate $R(x, y)$ let us fix on one particular formal counterpart of this predicate, which we denote by $\sigma_K(x, y)$. Then for any $n \in \mathbb{N}$ the statement $\exists y \sigma_K(n, y)$ is a formal counterpart for '$n \in K$', and $\exists y \sigma_K(n, y)$ is a formal counterpart of '$n \notin K$'. Let us therefore write

$$n \in K \text{ for } \exists y \sigma_K(n, y)$$ 

and

$$n \notin K \text{ for } \exists y \sigma_K(n, y).$$

Then using lemma 1.2 we have immediately

1.3. Lemma

For any $n \in \mathbb{N}$

(a) $n \in K$ iff $n \in K \in \mathcal{F}$

(b) $n \notin K$ iff $n \notin K \in \mathcal{F}$

We are almost ready to answer the question 1.1(a) above; we shall need the following lemma.
1.4. Lemma

There is a total computable function $g$ such that for all $n$, $\theta_{g(n)}$ is $n \notin K$.

Proof. This is immediate from the effectiveness of the coding of statements, since given $n$ we can effectively write down the statement $n \notin K \equiv \neg \exists \forall \forall \forall (n, y)$.

Now we have, in answer to question 1.1(a):

1.5. Theorem

$\mathcal{T}$ is not r.e.; in fact $\mathcal{T}$ is productive.

Proof. Let $T = \{n : \theta_n \in \mathcal{T}\}$. Taking $g$ as in lemma 1.4 we have $n \in K \Leftrightarrow n \notin \mathcal{T}$ (by lemma 1.3),

$\Rightarrow g(n) \in T$ (by lemma 1.4).

So, since $K$ is not r.e., neither is $T$. In fact, by theorem 7.3.2 we see that $T$ is productive.

1.6. Exercise

Show that $\mathcal{T}$ is productive.

2. Incompleteness

A simple version of Gödel's incompleteness theorem follows easily from theorem 1.5. We must first describe the setting of this famous result.

Consider the second question (1.1(b)) posed in §1. This question is made precise by using the idea of a formal system, a formal system $(\mathcal{A}, \mathcal{B})$ (for the language $L$) consists of a set $\mathcal{A} \subseteq \mathcal{T}$ (the axioms) and an explicit definition $\mathcal{B}$ of the notion of a formal proof of a statement in $\mathcal{T}$ from these axioms, satisfying the conditions:

(2.1) (a) Proofs are finite objects (hence capable of being coded),

(b) The explicit definition $\mathcal{B}$ of proof is such that if $\mathcal{B}$ is recursive then the relation

$p \equiv \text{a proof of the statement } \sigma \text{ from the axioms } \mathcal{A}$

is decidable.

We can now interpret the question 1.1(b) as asking whether there is a formal system for $L$ such that

(2.2) (a) $\mathcal{A}$ is recursive (so we are taking simple-minded in a fairly wide sense),

(b) The provable statements are precisely those in $\mathcal{T}$.

The condition (b) poses a problem for the philosopher who may be trying to define the very notion of arithmetic truth by means of a formal system. For him, this condition is meaningless, and must be replaced by conditions reflecting some of the properties to be expected of truth, such as

(2.2)(b') Consistency: there is no statement $\sigma$ such that both $\sigma$ and $\neg \sigma$ are provable,

(2.2)(b") Completeness: for any statement $\sigma$, either $\sigma$ is provable or $\neg \sigma$ is provable.

A simplified version of Gödel's theorem shows that there is no formal system of arithmetic satisfying the conditions 2.2(a) and (b). This is easily derived from theorem 1.5, and is given below. The full theorem of Gödel [1931] together with its improvement by Rosser shows that there is no formal system of arithmetic (of a certain minimal strength) satisfying conditions 2.2(a) and (b'), (b''), in other words, any consistent formal system of arithmetic having a recursive set of axioms is incomplete. This will be proved in §3.

We shall need the following lemma to establish the simplified Gödel theorem.

2.3. Lemma

In any recursively axiomatised formal system the set of provable statements is r.e.

Proof. Let $\mathcal{F}$ be the set of statements in $\mathcal{T}$ that are provable. Since proofs are finite, they can be effectively numbered; then if $\mathcal{A}$ is a recursive set of axioms the predicate

$M(x, y) \equiv \text{y is the number of a proof of } \theta_x \text{ from the axioms } \mathcal{A}$

is decidable, by (2.1(b)). Then

$\theta_x \text{ is provable } \Leftrightarrow \text{there is } y \text{ such that } M(x, y) \text{ holds.}$

Hence, by theorem 7-2.4, $\mathcal{F}$ is r.e.

Now we have

2.4. Theorem. (The simplified Gödel incompleteness theorem)

Suppose that $(\mathcal{A}, \mathcal{B})$ is a recursively axiomatised formal system in which all provable statements are true. Then there is a statement $\sigma$ that is true but not provable (and consequently $\neg \sigma$ is not provable either).
Proof. By lemma 2.3, the set $\mathcal{P}$ of provable statements is r.e., and we are given that $\mathcal{P} \subseteq \mathcal{T}$. Now $\mathcal{T}$ is not r.e. (theorem 1.5) so we immediately have a statement $\sigma \in \mathcal{T}\setminus\mathcal{P}$; i.e. $\sigma$ is true but not provable. Clearly $\neg \sigma$ is not provable either (otherwise $\neg \sigma$ would be true). \square

(Using the productivity of $\mathcal{T}$ (theorem 1.5) we could strengthen this theorem to say that the statement $\sigma$ can be obtained effectively from a specification of the formal system (which would yield an index for $\mathcal{P}$).

To aid an understanding of the proof of the full Gödel theorem in § 3 it is useful to examine the inner workings that were hidden when we applied theorem 1.5 in the above proof to obtain the statement $\sigma$.

Let us say that a statement is refutable if its negation is provable. Consider the sets of numbers $\text{Pr}^*$ and $\text{Ref}^*$ given by

$$\text{Pr}^* = \{n: n \in K \text{ is provable}\},$$

$$\text{Ref}^* = \{n: n \in K \text{ is refutable}\} = \{n: n \in K \text{ is provable}\} = \{n: \theta(n) \in \mathcal{P}\},$$

(where $\theta$ is the computable function given by lemma 1.4 and used in the proof of theorem 1.5). The assumption that provable statements are true means in particular that $\text{Pr}^* \subseteq K$ and $\text{Ref}^* \subseteq K$. Now $\text{Ref}^*$ is r.e. (from the fact that $n \in \text{Ref}^* \iff \theta(n) \in \mathcal{P}$, and $\mathcal{P}$ is r.e.), so there is a number $m$ such that $\text{Ref}^* = W_m$.

By the productivity of $K$ we have immediately that $m \in K \setminus \text{Ref}^*$, i.e. $m \notin K$, and $m \notin K$ is not provable. Taking $\sigma$ to be the statement $m \notin K$ we thus see that $\sigma$ is true but not provable (and $\neg \sigma$ is not provable, as before). The argument is illustrated by fig. 8a. (For comparison with the

Fig. 8a. Simplified Gödel incompleteness (theorem 2.4).

proof of the full Gödel theorem in the next section, note that the non-provability of $\neg \sigma$ can be seen as a consequence of the fact that $\text{Pr}^* \subseteq K$: for $m \in K$ (as above), so $m \notin \text{Pr}^*$, i.e. $m \notin K$ is not provable. Then, by the rules of formal proof $\neg m \in K$ (i.e. $\neg \sigma$ is not provable).

Notice now the intended meaning of the statement $\sigma$ thus obtained: $\sigma$ is the formal counterpart of the statement $m \notin K$, i.e. $m \notin W_m$. But we have

$$m \notin W_m \iff m \notin \text{Ref}^*$$

$$\iff m \notin K \text{ is provable}$$

$$\iff \theta(n) \in \mathcal{P}$$

Thus $\sigma$ is a formal counterpart of the statement '$\sigma$ is not provable'; i.e. speaking rather loosely, $\sigma$ says 'I am not provable'. This is reminiscent of the paradox of the liar, involving the informal statement

$$A = \text{I am lying}.$$

Informal reasoning about $A$ results in the paradox

$$A \text{ is true} \iff A \text{ is not true}.$$

If the same informal reasoning is applied to the informal statement 'I am not provable' the paradox is avoided by the conclusion that provable is not the same as true. This informal conclusion is rigorously justified by the proof of theorem 2.4.

3. Gödel's incompleteness theorem

We proceed in this section to show how the idea behind the proof of theorem 2.4 can be refined so as to avoid any reference to truth.

For the moment we fix on a particular formal system of arithmetic known as Peano arithmetic. The axioms for this system consist of a recursive subset of $\mathcal{S}$ known as Peano's axioms: these reflect the simple properties of the successor operation on $\mathbb{N}$, and the recursive definition of addition and multiplication in terms of it, together with an axiom scheme reflecting the principle of induction on $\mathbb{N}$. The notion of a formal proof is taken as that defined for the first-order predicate calculus. Full details of Peano arithmetic (sometimes called formal number theory) may be found in any textbook on mathematical logic. For our purposes, the important fact we need to know about Peano arithmetic is given by the following lemma, to which a substantial part of Gödel's proof is devoted.

3.1. Lemma

Let $M(x_1, \ldots, x_n)$ be a decidable predicate, and let $\sigma(x_1, \ldots, x_n)$ be the statement of $I$ that is the formal counterpart of $M(x_1, \ldots, x_n)$ as:
given by lemma 1.2. Then $M$ is represented in Peano arithmetic in the following sense: for any $a_1, \ldots, a_n \in \mathbb{N}$,

(a) if $M(a_1, \ldots, a_n)$ holds, then $\sigma(a_1, \ldots, a_n)$ is provable,
(b) if $M(a_1, \ldots, a_n)$ does not hold, then $\neg \sigma(a_1, \ldots, a_n)$ is provable.

(For a proof refer to a textbook such as Mendelson [1964].) □

Consider now the statement $n \in K$ (i.e. $\exists y \varphi(x, y)$) that we took in § 1 as a formal counterpart of the statement $n \in K$. Then from lemma 3.1 we can obtain

3.2. Corollary

For any natural number $n$, if $n \in K$ then $n \in K$ is provable in Peano arithmetic.

Proof. Suppose that $a \in K$. Then there is a natural number $m$ such that $R(n, m)$ holds, so by lemma 3.1 we have that $\sigma_R(n, m)$ is provable. The rules of the predicate calculus are such that we can immediately find a proof of $\exists y \varphi(n, y)$, i.e. $n \in K$ is provable.

For part of his proof, Gödel needed an extra technical condition called $\omega$-consistency: a formal system is said to be $\omega$-consistent if there is no statement $\tau(y)$ such that all of the following are provable:

$$\exists y \tau(y), \neg \tau(0), \neg \tau(1), \neg \tau(2), \ldots$$

($\omega$-consistency is a stronger condition than consistency (2.2)(b')).

We can easily derive the converse of corollary 3.2 from lemma 3.1, with the assumption of $\omega$-consistency.

3.3. Lemma

Suppose that Peano arithmetic is $\omega$-consistent; then for any natural number $n$, if $n \in K$ is provable then $n \in K$.

Proof. Suppose that $n \in K$; then for every $m \in \mathbb{N}$ we have that $R(n, m)$ does not hold, so by lemma 3.1, $\neg \sigma_R(n, m)$ is provable. Thus, if $n \in K$ is provable but $n \not\in K$, all of the following are provable

$$\exists y \sigma_R(n, y), \neg \sigma_R(n, 0), \neg \sigma_R(n, 1), \ldots$$

in contradiction of $\omega$-consistency for the statement $\tau(y) = \sigma_R(n, y)$. □

We can now present a proof of

3.4. Theorem (Gödel's incompleteness theorem [1931])

There is a statement $\sigma$ of $L$ such that

(a) if Peano arithmetic is consistent, then $\sigma$ is not provable.
(b) if Peano arithmetic is $\omega$-consistent, then $\neg \sigma$ is not provable.

Proof.

(a) Recall the sets $\text{Pr}^* = \{n : n \in K \text{ is provable}\}$,

$$\text{Ref}^* = \{n : n \in K \text{ is refutable}\}$$

that we defined in the discussion at the end of the previous section. By corollary 3.2 we have $K \subseteq \text{Pr}^*$; consistency implies that $\text{Pr}^* \cap \text{Ref}^* = \emptyset$, and so $\text{Ref}^* \subseteq K$. We can now argue as before: $\text{Ref}^*$ is r.e., so take $m$ such that $\text{Ref}^* = W_m$. The situation is illustrated by fig. 8a, which should be compared with that in fig. 8a.

By the productiveness of $K$, we have that $m \in K \setminus \text{Ref}^*$; in particular, $m \in \text{Ref}^*$ means that $m \in K$ is not provable. Hence (a) is established, by taking $\sigma$ to be the statement $m \in K$.

(b) The condition of $\omega$-consistency implies (by lemma 3.3) that $\text{Pr}^* \subseteq K$, and hence $\text{Pr}^* = K$. Thus, with $\omega$-consistency, fig. 8b is modified to become fig. 8c. Thus $m \in K$ means that $m \in \text{Pr}^*$; i.e. $m \in K$ is not provable. The rules of the predicate calculus tell us immediately that $\neg \sigma$ (i.e. $\neg m \in K$) is not provable. □

Notes

1. The statement $\sigma$ produced by Gödel's theorem is called an undecidable or an undecided statement of Peano arithmetic. As discussed at the

Fig. 8b. Gödel incompleteness (theorem 3.4(a)).
end of § 2. σ has the informal meaning 'I am not provable', and is, on an intuitive level, true.

2. Clearly Gödel's theorem applies to any recursively axiomatised formal system in which all decidable relations can be represented (in the sense of lemma 3.1). In particular, this is true for any such system that is stronger than Peano arithmetic. In consequence, there is no way to avoid the incompleteness phenomenon by adding new axioms: for example σ or ¬σ. The resulting formal system would have a new undecided statement.

3. Note that the undecided statement σ can be constructed explicitly from a specification of Peano arithmetic, since from such a specification, we could effectively find an index m for Refσ. This constructive aspect of Gödel's theorem is a consequence of the fact that K is creative. An analysis of the proof would show that we can demonstrate the mere existence of an undecided statement using any non-recursive r.e. set A in place of K.

4. Although not entirely clear from our presentation, the proof of part (a) of Gödel's theorem is a finitist proof: that is, it shows explicitly how, given a formal proof of the statement σ, to construct a proof of ¬σ (thus demonstrating inconsistency). We cannot make the same remark about (b), because σ-consistency is not a finitist notion.

In 1936 J. B. Rosser saw how to eliminate the assumption of σ-consistency in part (b) of Gödel's theorem. We shall now see that Rosser's refinement of Gödel's method can be viewed as an application of the effective recursive inseparability of the r.e. sets

\[ K_0 = \{ x : \phi_e(x) = 0 \} \text{ and } K_1 = \{ x : \phi_e(x) = 1 \} \]

that we discussed in exercise 7.3.13, in place of the use of the creative set K. Our treatment below does not assume familiarity with this exercise.

We begin by describing some statements of F that are formal counterparts of the statements \( n \in K_0 \) and \( n \in K_1 \); these are slightly more complex than the formal version of \( n \in K \) used earlier. Select decidable predicates \( R_0(x, y) \) and \( R_1(x, y) \) such that

\[ n \in K_0 \iff \text{there is } y \text{ such that } R_0(n, y) \]

and

\[ n \in K_1 \iff \text{there is } y \text{ such that } R_1(n, y). \]

Now clearly \( K_0 \cap K_1 = \emptyset \), so we also have

\[ \forall n \in K_0 \iff \text{there is } y \text{ such that (i) } R_0(n, y) \text{ and (ii) for all } z \leq y, R_1(n, z) \text{ does not hold,} \]

and there is a similar equivalence for \( n \in K_1 \). Now take statements \( \sigma_{R_0}, \sigma_{R_1} \), representing \( R_0, R_1 \) in Peano arithmetic as given by lemma 3.1. Rosser's trick was (essentially) to use the following statement (based on (**) above)

\[ \exists y(\sigma_{R_0}(n, y) \land \forall z \leq y(\neg \sigma_{R_1}(n, z))) \]

as the formal counterpart of \( n \in K_0 \), rather than the simpler statement \( \exists y \sigma_{R_0}(n, y) \). Let us write \( n \in K_0 \) for the statement (***) above. Similarly we write \( n \in K_1 \) for the statement:

\[ \exists y(\sigma_{R_1}(n, y) \land \forall z \leq y(\neg \sigma_{R_0}(n, z))). \]

Now it is quite straightforward to establish the following key lemma (which should be compared with corollary 3.2):

3.5. \textbf{Lemma}

In Peano arithmetic, for any natural number \( n \)

(a) if \( n \in K_0 \), then \( n \in K_0 \) is provable,

(b) if \( n \in K_1 \), then \( n \in K_1 \) is provable,

(c) if \( n \in K_1 \) is provable, then \( n \notin K_0 \) is also provable.

The proof of this lemma uses some technical properties of Peano arithmetic, and we therefore omit it. It is to obtain 3.5(c) particularly that the more complex formal representations of \( n \in K_0 \) and \( n \in K_1 \) are needed. (For those familiar with mathematical logic we should mention that lemma 3.5 is easily established once the following statements have been shown to be provable in Peano arithmetic:
(3.6) (a) For any \( m \in \mathbb{N} \):
\[ \forall z \in m(z = 0 \lor z = 1 \lor \ldots \lor z = m) \]
(b) \( \forall y \forall z (y = z \lor z = y) \)

We can now complete the proof of

3.7. Theorem (The Gödel-Rosser incompleteness theorem)

There is a statement \( \tau \) such that if Peano arithmetic is consistent, neither \( \tau \) nor \( \neg \tau \) is provable.

Proof. Define the sets

\[ \text{Pr}^{**} = \{ n : n \in K_0 \text{ is provable} \} \]
\[ \text{Ref}^{**} = \{ n : n \in K_0 \text{ is refutable} \} \]
\[ = \{ n : n \notin K_0 \text{ is provable} \} \]

Consistency means that \( \text{Pr}^{**} \cap \text{Ref}^{**} = \emptyset \).

From lemma 3.5(a) we have

\[ K_0 \subseteq \text{Pr}^{**} \]

Also, for any \( n \), combining lemma 3.5(b) and (c) we have

\[ n \in K_1 \Rightarrow n \notin K_0 \text{ is provable} \]

i.e.

\[ K_1 \subseteq \text{Ref}^{**} \]

Now \( \text{Pr}^{**} \) and \( \text{Ref}^{**} \) are both r.e. (this uses the fact that \( \mathcal{P} \) is r.e.) so the recursive inseparability of \( K_0 \) and \( K_1 \) (exercise 7.2.18(13b)) means that there is a number \( p \notin \text{Pr}^{**} \cap \text{Ref}^{**} \). The state of affairs is illustrated in fig. 8d. Now \( p \notin \text{Pr}^{**} \) means that \( p \notin K_0 \) is not provable, and \( p \notin \text{Ref}^{**} \) means

Fig. 8d. Gödel-Rosser incompleteness (theorem 3.7).

that \( p \notin K_0 \) is not provable, so the theorem is established, by taking \( \tau \) to be the statement \( p \in K_0 \).

Although the proof of the theorem as stated is complete, let us now see how the number \( p \) (hence the statement \( \tau \)) can be explicitly constructed. From an explicit specification of Peano arithmetic, we can effectively find an index \( p \) such that

\[ \phi_p(n) =
\begin{cases} 
1 & \text{if } n \notin \text{Pr}^{**}, \\
0 & \text{if } n \in \text{Ref}^{**}, \\
\text{undefined} & \text{otherwise}.
\end{cases} \]

We can now see that \( p \notin \text{Pr}^{**} \cup \text{Ref}^{**} \), as follows:

(i) If \( p \in \text{Pr}^{**} \), then \( \phi_p(p) \equiv 1 \), so \( p \in K_1 \), hence \( p \in \text{Ref}^{**} \), contradicting consistency. Hence \( p \notin \text{Pr}^{**} \).

(ii) If \( p \in \text{Ref}^{**} \), then \( \phi_p(p) \equiv 0 \), so \( p \notin K_0 \), hence \( p \notin \text{Pr}^{**} \), another contradiction. Hence \( p \notin \text{Ref}^{**} \).

(The fact that \( p \) can thus be obtained explicitly uses essentially the effective recursive inseparability of \( K_0 \) and \( K_1 \) (see exercise 7.3.13(9))).

Notes

1. The statement \( \neg \tau \) constructed in this theorem corresponds to the undecidability of \( \phi \) of theorem 3.4; it is easily seen that \( \neg \tau \) also has the informal interpretation 'I am not provable', and is intuitively true.

2. The Gödel-Rosser theorem applies to any recursively axiomatised formal system of arithmetic in which all decidable relations can be represented and for which lemma 3.5 can be established. (Lemma 3.5 always holds for systems in which statements 3.6(a), (b) can be proved: such systems are called Rosser systems.) Again, there is thus no possibility of avoiding incompleteness by adding new axioms.

3. The Gödel-Rosser theorem is a completely finitist theorem: the proof (when given in full detail) shows how to demonstrate inconsistency explicitly if we were given a proof of either \( \tau \) or \( \neg \tau \).

4. Undecidability

We have already seen that the set \( \mathcal{F} \) of true statements of arithmetic is not recursive (theorem 1.5): this is often described by saying that \( \mathcal{F} \) is undecidable. In general, when considering sets of statements the terms decidable and undecidable are often used to mean recursive and non-recursive.

We can ask particularly of any formal system of arithmetic, is the set \( \mathcal{P} \) of provable statements decidable? The answer is invariably no, and there
are various ways to see this. We confine ourselves to one of the many results in this area, using the ideas of the previous section.

4.1. Theorem
Suppose that \((\mathcal{A}, \mathcal{O})\) is an \(\omega\)-consistent formal system of arithmetic in which all decidable predicates are representable (in the sense of lemma 3.1). Then the set of provable statements is creative.

Proof. The assumption of the theorem means that Gödel's theorem 3.4 applies, so in particular we have from the proof of theorem 3.4:

\[ K = \text{Pr}^* = \{ n : n \in K \text{ is provable} \}. \]

Now let \( \text{Pr} = \{ n : \theta_n \text{ is provable} \} \); we can find a computable function \( h \) such that \( n \in K \Leftrightarrow \theta_n \in \text{Pr}^* \)

\[ \Leftrightarrow h(n) \in \text{Pr}. \]

So by theorem 7-3.2, Pr is creative. \( \square \)

4.2. Corollary
If Peano arithmetic is \(\omega\)-consistent then the provable statements form a creative set. (This is the case in particular if all provable statements are true.)

The counterpart to theorem 4.1 and corollary 4.2 using Rosser's ideas is given in the following exercise.

4.3. Exercise
Suppose that \((\mathcal{A}, \mathcal{O})\) is a consistent recursively axiomatised formal system for which lemmas 3.1 and 3.5 hold. Let \( \text{Pr}^* \) and \( \text{Ref}^* \) be the sets defined in the proof of theorem 3.6.

(a) Show that \( \text{Pr}^* \) and \( \text{Ref}^* \) are effectively recursively inseparable.

(b) Let \( \text{Pr} = \{ n : \theta_n \text{ is provable} \} \) and \( \text{Ref} = \{ n : \neg \theta_n \text{ is provable} \} \). Prove that \( \text{Pr} \) and \( \text{Ref} \) are effectively recursively inseparable. (Hint. Extend the idea of theorem 7-3.2 to pairs of effectively recursively inseparable sets.)

The presentation of the results in this chapter is derived largely from the books of Kleene [1967] and Smullyan [1961]. For further discussion of incompleteness and undecidability in arithmetic and related areas, the reader is referred to Bell & Machover [1977], Boolos & Jeffrey [1974], or Rogers [1971].

9 Reducibility and degrees

In earlier chapters we have used the technique of reducing one problem to another, often as means of demonstrating undecidability. We did this, for instance, in the proof of theorem 6-1.4 by showing that there is a total computable function \( k \) such that \( x \in W_n \Leftrightarrow \phi_{k(n)} = 0 \), i.e., we used the function \( k \) to transform or reduce each instance of the general problem \( x \in W_n \) to an instance of the general problem \( \phi_x = 0 \). In this chapter we consider two ways of making the idea of reducibility precise, and for each we discuss the associated notion of degree (of difficulty) that arises.

It is more convenient to deal with reducibility between sets rather than between problems, remembering that any problem is represented by a set of numbers. The informal idea of a set \( A \) being reducible to a set \( B \) can be expressed in various ways: for instance

(a) 'Given a decision procedure for the problem \( x \in B \), we can construct one for \( x \in A \).'

(b) 'For someone who knows all about \( B \), there is a mechanical procedure (that uses his knowledge of \( B \)) for deciding questions about \( A \).'

(c) 'Questions about \( A \) are no harder than questions about \( B \).'

(d) 'The degree of difficulty of the problem \( x \in A \) is no greater than that of the problem \( x \in B \).'

It turns out that there are several non-equivalent ways of making this idea precise. The differences between these consist in the manner and extent to which information about \( B \) is allowed to be used to settle questions about \( A \). In §§ 1–3 we shall investigate one of the simplest notions of reducibility, called many-one reducibility, which includes all of our earlier uses of the informal idea. In the final sections we shall discuss a more general notion known as Turing reducibility.
1. Many-one reducibility

1.1. Definition

The set $A$ is many-one reducible (abbreviated $m$-reducible) to the set $B$ if there is a total computable function $f$ such that for all $x$

$$x \in A \iff f(x) \in B.$$ 

We shall write this $A \equiv_m B$; and we shall write $f : A \equiv_m B$ to indicate that $f$ is a total computable function demonstrating that $A \equiv_m B$.

Note. The phrase many-one is used to distinguish this kind of reducibility from a related notion called one-one reducibility, for which the function $f$ is required to be injective.

We have used $m$-reducibility implicitly on many occasions in earlier chapters. The $\equiv_m \equiv_n$ theorem is often needed to establish many-one reducibility, as we see in the following examples.

1.2. Examples

1. In chapter VI we showed that $K$ is $m$-reducible to each of the following sets:

(a) $\{x : \phi_x = 0\}$ (theorem 6.1.4, quoted above),
(b) $\{x : c \in W_x\}$ (theorem 6.1.6).

2. If we examine the function $k$ given in the proof of theorem 6.1.6 we see that $x \in K \iff \phi_{k(x)}$ is total. Hence

$$k : K \equiv_m \{x : \phi_x \text{ is total}\}.$$ 

3. Rice's theorem (theorem 6.1.7) is proved by showing that $K \equiv_m \{x : \phi_x \in \mathcal{S}\}$, where $\mathcal{S}$ is any non-empty subset of $\mathcal{C}$ such that $\phi_x \in \mathcal{S}$.

4. $\{x : \phi_x \text{ is total}\} \equiv_m \{x : \phi_x = 0\}$.

Proof. Using the $s$-$m$-$n$ theorem obtain a total computable function $k$ such that $\phi_{k(x)} = \phi_x$ for all $x$. Then

$$k : \{x : \phi_x \text{ is total}\} \equiv_m \{x : \phi_x = 0\}.$$ 

The following theorem gives some of the elementary properties of $m$-reducibility.

1.3. Theorem

Let $A$, $B$, $C$ be sets.

(a) $\equiv_m$ is reflexive (i.e. $A \equiv_m A$) and transitive (i.e. if $A \equiv_m B$ and $B \equiv_m C$ then $A \equiv_m C$).

(b) $A \equiv_m B \iff A \equiv_m B$.

(c) if $A$ is recursive and $B \leq_m A$, then $B$ is recursive,

(d) if $A$ is recursive and $B \neq \emptyset$, then $A \leq_m B$,

(e) if $A$ is r.e. and $B \leq_m A$, then $B$ is r.e.,

(f) (i) $A \equiv_m N \iff A = N$,

(ii) $A \equiv_m \emptyset \iff A = \emptyset$,

(g) (i) $N \equiv_m A \iff A \neq \emptyset$,

(ii) $\emptyset \equiv_m A \iff A \neq N$.

Proof

(a) Reflexive. $t : A \leq_m A$, where $t$ is the identity function. Transitive. If $f : A \leq_m B$ and $g : B \leq_m C$, then clearly $g \circ f : A \leq_m C$.

(b) If $g : A \leq_m B$, then $x \in A \iff g(x) \in B$; hence $x \in A \iff g(x) \in B$; hence $g : A \leq_m B$.

(c) Suppose that $g : B \leq_m A$; then $c_n(x) = c_A(g(x))$, so $c_n$ is computable.

(d) Choose $h \in B$ and $c \in B$, and define $f$ by

$$f(x) = \begin{cases} b & \text{if } x \in A, \\ c & \text{if } x \notin A. \end{cases}$$

Then $f$ is computable (since $A$ is recursive), and $x \in A \iff f(x) \in B$; hence $f : A \leq_m B$.

(e) Suppose that $g : B \leq_m A$ and $A = \text{Dom}(h)$, with $h$ computable; then $B = \text{Dom}(h \circ g)$, and $h \circ g$ is computable, so $B$ is r.e.

(f) (i) By (a), $N \equiv_m N$. Conversely, suppose that $f : A \leq_m N$; i.e., $x \in A \iff f(x) \in N$. Then clearly $A = N$.

(ii) is dual to (i): $A \equiv_m \emptyset \iff \overline{A} \equiv_m N \iff A = \emptyset$.

(g) (i) Suppose that $f : N \leq_m A$; then $A = \text{Ran}(f)$, so $A \neq \emptyset$ (since $f$ is total). Conversely, suppose that $A \neq \emptyset$, and choose $c \in A$. Then if we define $g(x) = c$ (all $x$), we have $g : N \leq_m A$.

(ii) is dual to (i): $\emptyset \leq_m A \iff N \equiv_m A \iff A \neq \emptyset \neq N$. □

From (c) of this theorem we obtain the following example of non-reducibility:

1.4. Corollary

Neither of the sets $\{x : \phi_x \text{ is total}\}, \{x : \phi_x \text{ is not total}\}$ is $m$-reducible to $K$.

Proof. From corollary 7.2.17 neither of these sets is r.e.; apply theorem 1.3(e). □
The exceptional behaviour of the sets $\emptyset$, $\mathbb{N}$ as given in theorem 1.3(d), (f), (g) is part of the price that has to be paid for the simplicity of the notion of $m$-reducibility. Another rather unsatisfactory feature is that the sets $A$ and $\bar{A}$ are not necessarily inter-reducible (contrary to the intuition that the problems $\langle x \in A \rangle$ and $\langle x \notin A \rangle$ should be equally difficult), as we now see:

1.5. Corollary

If $A$ is an r.e. set that is not recursive, then $\bar{A}$ is not $m$-equivalent to $A$.

Proof. By theorem 1.3(e) if $\bar{A}$ is not $m$-equivalent to $A$, then $\bar{A}$ is r.e.-a contradiction. For $A$ is recursive, use theorem 1.3(b). □

The next result shows again the key role played by the r.e. set $K$.

1.6. Theorem

A set $A$ is r.e. if and only if $A \leq_m K$.

Proof. If $A \leq_m K$, then theorem 1.3(e) tells us that $A$ is r.e. Conversely, let $A$ be any r.e. set. Define a computable function $f(x)$ by

$$f(x, y) = \begin{cases} 1 & \text{if } x \in A, \\ \text{undefined} & \text{if } x \notin A. \end{cases}$$

The $s$-m-n theorem gives a total computable function $s(x)$ such that $f(x, y) = \phi_{s(x)}(y)$. It is clear from the definition of $f$ that

$$x \in A \iff \phi_{s(x)}(s(x)) \text{ is defined} \iff s(x) \in K.$$

i.e. $A \leq_m K$. □

This theorem may be interpreted as saying that the problem $\langle x \in K \rangle$ is the most difficult partially decidable problem.

1.7. Exercises

1. Show that $K$ is $m$-reducible to each of the following sets:

   (a) $\{x : \phi_i(x) = 0\}$,
   (b) $\{x : x \in E_i\}$.

2. Show that for any sets $A$, $B$, if $B \neq \emptyset$ then $A \leq_m A \oplus B$. (Recall that $A \oplus B = \{\pi(a, b) : a \in A, b \in B\}$.)

3. Show that

   (a) $\{x : \phi_i = 0\} \leq_m \{x : \phi_i \text{ is total and constant}\}$.
   (b) $\{x : \phi_i \text{ is total}\} \leq_m \{x : W_i \text{ is infinite}\}$.

4. Show that none of the sets in exercise 3 above is $m$-reducible to an r.e. set.

5. Suppose that $A$, $B$ are r.e. sets such that $A \cup B = \mathbb{N}$ and $A \cap B \neq \emptyset$. Prove that $A \leq_m A \cap B$.

2. Degrees

For any notion of reducibility there is an associated notion of equivalence between sets: this corresponds to the informal idea of two sets or problems having the same degree of difficulty. Thus, for $m$-reducibility we have:

2.1. Definition

The sets $A$ and $B$ are many-one equivalent (abbreviated $m$-equivalent) if $A \leq_m B$ and $B \leq_m A$. We write this $A =_m B$.

The use of the word equivalent in this definition is justified by

2.2. Theorem

The relation $=_m$ is an equivalence relation. (See Prologue §3 for definition.)

Proof. Reflexivity and transitivity follow immediately from theorem 1.3(a); symmetry is obvious from the definition. □

2.3. Examples

1. Let $c$ be any number; then $\{x : c \in W_i\} \equiv_m K$, by example 1.2(1b) and theorem 1.6.

2. For every recursive set $A$ other than $\emptyset$, $\mathbb{N}$, we have $A \equiv_m \bar{A}$ by theorem 1.3(d).

3. If $A$ is r.e. but not recursive, then $A \not\equiv_m \bar{A}$, by corollary 1.5.

4. $\{x : \phi_i = 0\} \equiv_m \{x : \phi_i \text{ is total}\}$. One half of this is given by example 1.2(4); to see the reverse reduction, use the $s$-m-n theorem to obtain a total computable function $\phi$ such that

$$\phi_{s(x)}(y) = \begin{cases} 0 & \text{if } \phi_i(y) = 0, \\ \text{undefined} & \text{otherwise}. \end{cases}$$

Then clearly $\phi_i = 0 \equiv_m \phi_{s(x)}$ is total.

For any set $A$, the equivalence class of $A$ under the relation $\equiv_m$ is the class of sets $d_m(A)$ given by

$$d_m(A) = \{B : A \equiv_m B\}.$$

This can be thought of as the class of all those sets having the same degree
of difficulty (with respect to \( \leq_m \)) as the set \( A \); hence \( d_m(A) \) is called the \( m \)-degree of \( A \).

2.4. Definition

An \( m \)-degree is an equivalence class of sets under the relation \( =_m \), i.e., it is any class of sets of the form \( d_m(A) \) for some set \( A \).

It is conventional to use lower case bold face letters such as \( a, b, c \) to denote degrees.\(^1\) It is worth making a strong mental note that although lower case letters are used, these are sets of sets. Thus it is meaningful to write \( A \in a \), where \( a \) is a degree and \( A \) is a set, although at first this may appear a little odd.

The relation \( \leq_m \) on sets induces a partial ordering (see Prologue § 3 for definition) on \( m \)-degrees, also denoted \( \leq_m \), as follows:

2.5. Definition

Let \( a, b \) be \( m \)-degrees.

(a) \( a \leq_m b \) if there are \( A \in a \) and \( B \in b \) such that \( A \equiv_m B \).

(b) \( a <_m b \) if \( a \leq_m b \) but \( a \neq b \).

Note. It is immediate from the definition of \( =_m \) that \( a \equiv_m b \) if \( A \equiv_m B \) for every \( A \in a \), \( B \in b \).

2.6. Theorem

The relation \( \equiv_m \) is a partial ordering of \( m \)-degrees.

Proof. From theorem 1.3(a) we immediately that \( a \equiv_m a \) (reflexivity) and that \( a \equiv_m b, b \equiv_m c \) implies \( a \equiv_m c \) (transitivity). Suppose now \( a \equiv_m b \) and \( b \equiv_m a \). We have to show that \( a = b \). Let \( A \in a \) and \( B \in b \); then from the definition we have \( A \equiv_m B \) and \( B \equiv_m A \), so \( A =_m B \). Hence \( a = b \). \( \square \)

The name recursive \( m \)-degree is given to any \( m \)-degree that contains a recursive set; similarly, an \( r.e. \) \( m \)-degree is one that contains an \( r.e. \) set.\(^1\) We can translate parts of theorem 1.3 and theorem 1.6 into the language of degrees as follows.

2.7. Theorem

(a) \( \emptyset \) and \( \mathbb{N} \) are \( m \)-degrees, which we denote by \( \mathbf{0} \) and \( \mathbf{1} \) respectively; \( \mathbf{0} \) and \( \mathbf{1} \) are recursive \( m \)-degrees.

Although we have also used \( a \) on occasions to denote an \( n \)-tuple \( (a_1, \ldots, a_n) \), the context will resolve any possible ambiguity.

(b) There is one other recursive \( m \)-degree, denoted \( 0_m \), that consists of all recursive sets except \( \emptyset \) and \( \mathbb{N} \). Moreover, \( 0_n \leq_m a \) for any \( m \)-degree \( a \) other than \( 0, \mathbf{0} \).

(c) For any \( m \)-degree \( a \), we have \( \mathbf{0} \leq_m a \) provided \( a \neq \mathbf{0} \), and \( \mathbf{1} \leq_m a \) provided \( a \neq \mathbf{0} \).

(d) Any \( r.e. \) \( m \)-degree consists only of \( r.e. \) sets.

(e) If \( a \leq_m b \) and \( b \) is an \( r.e. \) \( m \)-degree, then \( a \) is also an \( r.e. \) \( m \)-degree.

(f) There is a maximum \( r.e. \) \( m \)-degree, namely \( d_m(K) \), which is denoted \( 0_m' \).

Proof.

(a) Follows from theorem 1.3(f);

(b) from theorem 1.3(c), (d);

(c) from theorem 1.3(g);

(d) from theorem 1.3(e);

(e) from theorem 1.3(e);

(f) from theorem 1.6. \( \square \)

Theorem 2.7 gives us a picture of the \( m \)-degrees as shown in fig. 9a. (In this diagram, we position a degree \( a \) below a degree \( b \) to indicate that \( a \leq_m b \).) We shall see later (as this picture suggests) that there are \( r.e. \) \( m \)-degrees other than \( 0_m \) and \( 0_m' \).

The structure of the collection of \( m \)-degrees under their partial ordering has been studied extensively. The following theorem means that this structure is what is known as an upper semi-lattice.

Fig. 9a. The \( m \)-degrees.
2.8. Theorem
Any pair of m-degrees \( a, b \) have a least upper bound; i.e., there is an m-degree \( c \) such that:
(i) \( a \leq m c \) and \( b \leq m c \) (c is an upper bound);
(ii) \( c \leq m \) any other upper bound of \( a, b \).
Proof. Pick \( A \in a, B \in b \) and let \( C = A \oplus B \), i.e.,
\[ C = \{2x : x \in A \} \cup \{2x + 1 : x \in B \}. \]
Then \( x \in A \Rightarrow 2x \in C \), so \( A \leq m C \), and \( x \in B \Rightarrow 2x + 1 \in C \), so \( B \leq m C \).
Thus, putting \( c = d \cup C \) we have that \( c \) is an upper bound of \( a, b \).

Suppose now that \( d \) is an m-degree such that \( a \leq m d \) and \( b \leq m d \).
Choose a set \( D \in d \), and suppose that \( f : A \leq m D \) and \( g : B \leq m D \). Then we have
\[ x \in C \Leftrightarrow (x \text{ is even \& } f(x) \in D) \text{ or } (x \text{ is odd \& } g(\frac{1}{2}(x - 1)) \in D) \]
Thus we have \( h : C \leq m D \) if we define \( h \) by
\[ h(x) = \begin{cases} f(x) & \text{if } x \text{ is even}, \\ g(\frac{1}{2}(x - 1)) & \text{if } x \text{ is odd}. \end{cases} \]
Hence \( e \leq m d \). \( \Box \)

It is clear that the least upper bound \( e \) of any pair of m-degrees \( a, b \) is uniquely determined; moreover, it is easy to see that if \( a, b \) are r.e. so is \( e \) (see exercise 2.9(5) below).

When considering the structure of the m-degrees, it is natural to examine in particular the structure of the r.e. m-degrees. (These include, of course, the recursive m-degrees \( 0_m, \omega, n \). We have already seen in theorem 2.7 (and indicated in fig. 9a) the following basic facts about r.e. m-degrees:
(a) if we ignore the exceptional m-degrees \( 0, n \) there is a minimum r.e. m-degree \( 0_m \) (in fact \( 0_m \) is minimum among all m-degrees);
(b) the r.e. m-degrees form an initial segment of the m-degrees; i.e., anything below an r.e. m-degree is also r.e.
(c) there is a maximum r.e. m-degree — namely \( 0_m^\prime \).

Moreover, it is easy to see that while there are uncountably many m-degrees, only countably many of these are r.e. (exercise 2.9(6) below).

It has emerged from much research over the past twenty-five years that the structure of the r.e. m-degrees is exceedingly complex. Within the scope of this book it is only possible to show that it is not completely simple; this we shall see in the next section.

2.9. Exercises
1. Show that each of the following sets is m-equivalent to \( K \):
   \( a \) \( \{x : x \in E \} \),
   \( b \) \( \{x : x \neq 0 \} \).
2. (a) Show that \( A = m A \oplus A \) for any set \( A \),
   (b) Let \( B \) be a non-empty recursive set. Show that \( A = m A \oplus B \) for any \( A \) provided that \( A \neq \emptyset \).
3. (Cf. examples 2.3(2, 3, 4).) Is it true that if \( A = m A \) then \( A \) is recursive? (See exercise 5d below.)
4. Show that the following sets all belong to the same m-degree:
   \( a \) \( \{x : x = 0 \} \),
   \( b \) \( \{x : x \text{ is total and constant} \} \),
   \( c \) \( \{x : W(x) \text{ is infinite} \} \).
5. Let \( a, b \) be m-degrees.\(^\text{3}\)
   (a) Show that the least upper bound of \( a, b \) is uniquely determined; denote this by \( a \cup b \);
   (b) Show that if \( a \leq m b \) then \( a \cup b = b \);
   (c) Show that if \( a, b \) are r.e., then so is \( a \cup b \);
   (d) Let \( A \in a \) and let \( a^* \) denote \( d_n(A) \). Check that \( a^* \) is independent of the choice of \( A \in a \).
6. (a) Show that any m-degree is denumerable (i.e., there are denumerably many sets \( A \in a \)).
   (b) Show that there are uncountably many m-degrees.
   (c) Show that there are countably many r.e. m-degrees.

3. m-complete r.e. sets
We have seen that \( 0_m \) the m-degree of \( K \) is maximum among all r.e. m-degrees. This is also described by saying that the set \( K \) is an m-complete r.e. set, or just an m-complete set.\(^3\) (There is a corresponding notion for any other kind of reducibility.)

3.1. Definition
A set is m-complete if it is r.e. and any r.e. set is m-reducible to it.

From theorem 1.6 we have immediately:

3.2. Theorem
\( K \) is m-complete.
(b) \( A \) is \( m \)-complete iff \( A =_m \mathcal{K} \) iff \( A \) is r.e. and \( \mathcal{K} \leq_m A \).
(c) \( 0_m \) consists exactly of all \( m \)-complete sets.

Applying this we have the following:

3.3. **Examples**

The following sets are \( m \)-complete:

(a) \( \{ x : x \in W_x \} \) (example 1.2(1b)),
(b) any non-trivial r.e. set of the form \( \{ x : \phi(x) \in \mathcal{B} \} \) where \( \mathcal{B} \in \mathcal{C}_1 \) (the proofs of theorems 7-3.4 and 3.8 show that \( \mathcal{K} \leq_m \mathcal{K} \) such a set),
(c) \( \{ x : \phi_2(x) = 0 \} \) (Exercise 1.7(1)).
(d) \( \{ x : x \in E_x \} \)

The reader may have realised that \( m \)-reducibility appeared implicitly in the statement of theorem 7-3.2, which implies immediately that

3.4. **Theorem**

Any \( m \)-complete set is creative.

*Proof.* If \( A \) is \( m \)-complete, then \( \mathcal{K} \leq_m A \), so \( \mathcal{K} \leq_m \mathcal{A} \), and by Theorem 7-3.2 \( \mathcal{A} \) is productive. \( \square \)

It is very pleasing to find that the converse of this theorem is also true, giving us a precise characterisation of \( m \)-complete sets:

3.5. **Theorem (Myhill)**

Creative sets are \( m \)-complete.

We must wait until chapter 11 for a new tool—the Second Recursion theorem—with which to prove this result. Note, however, that we have already established it for creative sets of indices in example 3.3(b).

As an immediate corollary to theorem 3.4 we can use simple sets to show that \( 0_m \) and \( 0' \) are not the only r.e. degrees:

3.6. **Corollary (to theorem 3.4)**

Simple sets are not \( m \)-complete; hence if \( A \) is the \( m \)-degree of any simple set, then \( 0_m \leq_m A \leq_m 0' \).

*Proof.* Simple sets are designed to be neither recursive nor creative. \( \square \)

This corollary justifies the inclusion of *something* between \( 0_m \) and \( 0' \) in fig. 9a; it does not, however, justify the suggestion in that picture that there is more than one non-recursive r.e. \( m \)-degree other than \( 0_m \). In fact there are infinitely many such \( m \)-degrees, although we shall not prove this here.

It is beyond the scope of this book to investigate further the structure of the \( m \)-degrees under their partial ordering \( \leq_m \), which, as already mentioned, is very complex. Much of this complexity can be deduced from results about the complex nature of the Turing degrees, which we discuss in the next sections.

4. **Relative computability**

We saw in § 1 that \( m \)-reducibility has two rather unsatisfactory features: the exceptional behaviour of \( \mathcal{O} \) and \( \mathcal{N} \), and the fact that we do not always have \( A =_m \mathcal{A} \). These features stem from the restricted nature of \( m \)-reducibility: we have \( A \leq_m B \) only if each question \( \forall x \in A ? \) can be settled by answering a single prescribed question about \( B \) in a prescribed way. The idea of Turing reducibility, which we shall define in § 5, is that \( \forall x \in A \) can be settled in a mechanical way by answering several questions about \( B \), the nature and (finite) number of which are not necessarily known in advance. This idea is made precise in terms of relative computability, which we describe in this section.

Suppose that \( \chi \) is any total unary function. Informally we say that a function \( f \) is *computable relative to \( \chi \)*, or just *\( \chi \)-computable*, if \( f \) can be computed by an algorithm that is effective in the usual sense, except that from time to time during computations we are allowed access to values of the function \( \chi \). Such an algorithm is called a *\( \chi \)-algorithm*. We can think of a \( \chi \)-algorithm as being linked to some external agent or *oracle* that can supply values of \( \chi \) on demand. The \( \chi \)-algorithm operates in a purely mechanical fashion, and a value \( \chi(n) \) is requested from the oracle only as dictated by the algorithm.

We can formulate a precise definition of relative computability using a modification of our URM, called an Unlimited Register Machine with Oracle, or URM0 for short.

4.1. **Definition**

The URM0 is like the URM in all respects except that it can recognize a fifth kind of instruction \( O(n) \) for every \( n \geq 1 \). The instruction \( O(n) \) is called an *oracle instruction*.

To be able to obey oracle instructions the URM0 must be linked to an *oracle*, which supplies values of some given function \( \chi \) on demand. We say then that the URM0 has the function \( \chi \) in its oracle. The function \( \chi \) is *not* thought of as part of the URM0 itself.

The response of the URM0 to an oracle instruction \( O(n) \) is as follows: if \( \chi \) is in the oracle, then replace \( r_n \) (the contents of register \( R_n \)) by \( \chi(r_n) \).
This is denoted in flow diagrams by

\[ r_n := \chi(r_n) \text{ or } \chi(r_n) \rightarrow R_n. \]

The URMO, with \( \chi \) in its oracle and obeying the instruction O(\( \alpha \)) may be envisaged as shown in fig. 9b.

A program is, as before, a finite sequence of instructions. The URMO operates under a URMO program \( P \) in the same way as the URM, with the following additional stipulation: after obeying an oracle instruction \( I_x \) in \( P \) the next instruction is \( I_{x+1} \).

We emphasise that in a URMO program \( P \) no particular function \( \chi \) is mentioned. Thus the meaning of \( P \) varies according to the function supplied in the oracle. However, a computation under \( P \) can be carried out only when a particular function \( \chi \) is supplied, so we write \( P^\chi \) to denote the program \( P \) when used with the function \( \chi \) in the oracle. Thus we write

\[ P^\chi(a_1, \ldots, a_n) \]

for the computation by \( P \), with \( \chi \) in the oracle, and with initial configuration \( a_1, a_2, \ldots, a_n, 0, 0, \ldots \); and we write

\[ P^\chi(a) \downarrow b \]

to mean that the computation \( P^\chi(a) \) stops with the number \( b \) in register \( R_1 \).

We can now make the following definitions (parallel with definition 1.3.1).

**Fig. 9b.**

![Diagram](image-url)

With resulting configuration

\[ r_1 \quad r_2 \quad r_3 \quad \chi(r_n) \]

### 4.2. Definition

Let \( \chi \) be a unary total function, and suppose that \( f \) is a partial function from \( \mathbb{N}^n \) to \( \mathbb{N} \).

(a) Let \( P \) be a URMO program. Then \( P \) URMO-computes \( f \) relative to \( \chi \) (or \( f \) is \( \chi \)-computed by \( P \)) if, for every \( a \in \mathbb{N}^n \) and \( b \in \mathbb{N} \),

\[ P^\chi(a) \downarrow b \iff f(a) = b. \]

(b) The function \( f \) is URMO-computable relative to \( \chi \) (or just \( \chi \)-computable) if there is a URMO program that URMO-computes it relative to \( \chi \).

We write \( \mathcal{E}^\chi \) to denote the class of all \( \chi \)-computable functions.

We are now in a position where we could define Turing-reducibility. However, to aid a better understanding of this concept when we come to it, we shall first outline a little of the development of the theory of relative computability.

Most methods and results from unrelativised computability have counterparts in relative computability. Thus in many of the theorems that follow we supply only a sketch proof or a reference to the unrelativised version of the same result. Throughout this section \( \chi \) stands for a total unary function.

### 4.3. Theorem

(a) \( \chi \in \mathcal{E}^\chi \),

(b) \( \mathcal{E} \subseteq \mathcal{E}^\chi \),

(c) if \( \chi \) is computable, then \( \mathcal{E} \subseteq \mathcal{E}^\chi \),

(d) \( \mathcal{E}^\chi \) is closed under substitution, recursion and minimalisation.

(e) if \( \psi \) is a total unary function that is \( \chi \)-computable, then \( \mathcal{E}^\psi \subseteq \mathcal{E}^\chi \).

**Proof.**

(a) Use the URMO program \( O(1) \).

(b) Any URM program is a URMO program.

(c) In view of (b), we need only show that \( \mathcal{E}^\chi \subseteq \mathcal{E} \). Suppose that \( f \) is \( \chi \)-computable and that \( \chi \) is computable. Proceeding informally, we can compute any value of \( f \) as follows: use the \( \chi \)-algorithm for \( f \), and whenever a value of \( \chi \) is requested simply compute it using the algorithm for \( \chi \). This is an effective procedure, so by Church's thesis \( f \) is computable. (We leave the reader to provide a formal proof of this result; see exercise 4.10(3).)
Other approaches to relativised computability. Any alternative approach to computability can be modified to provide a corresponding notion of relative computability. A relativised version of the Fundamental result (theorem 3-1.1) can then be proved, and this leads to the formulation of Church's thesis for relativised computability.

We mention here only the relativised notion of partial recursive function:

4.4. Definition
The class \( \mathcal{R}^\chi \) of \( \chi \)-partial recursive functions is the smallest class of functions such that
(a) the basic functions are in \( \mathcal{R}^\chi \),
(b) \( \chi \in \mathcal{R}^\chi \),
(c) \( \mathcal{R}^\chi \) is closed under substitution, recursion and minimalisation.

The phrases partial recursive in \( \chi \) or partial recursive relative to \( \chi \) are also used with the same meaning as \( \chi \)-partial recursive.

The notions \( \chi \)-recursive (or recursive in \( \chi \)) and \( \chi \)-primitive recursive (or primitive recursive in \( \chi \)) are defined in the obvious way.

Corresponding to theorem 3-2.2 (and proved in the same way) we have

4.5. Theorem
For any \( \chi \), \( \mathcal{R}^\chi = \mathcal{R}^\chi \).

Numbering programs and functions. URMO programs can be effectively numbered or coded by an easy adaptation of the method used in chapter 4 for URM programs. Let us assume that this has been done, so that we have a fixed effective enumeration (without repetitions)

\[ Q_0, Q_1, Q_2, \ldots \]

of all URMO programs. Then we write

\[ \phi_i^\chi \]

for the \( n \)-ary function \( \chi \)-computed by \( Q_n \).

\[ \phi_i^\chi \]

for \( \phi_i^\chi \).

\[ \mathcal{W}_n^{\chi} \]

for \( \text{Dom}(\phi_i^\chi) \).

\[ E_i^\chi \]

for \( \text{Ran}(\phi_i^\chi) \).

The \( m \)-\( m \)-\( n \)-theorem (4-4.3) has a relativised counterpart with identical proof:

4.6. Theorem (The relativised \( m \)-\( m \)-\( n \)-theorem)
For each \( m, n \geq 1 \) there is a total computable \((m + 1)\)-ary function \( s^n_m(e, x, y) \) such that for any \( \chi \)

\[ \phi_e^{(m+1)}(x, y) = \phi_{s^n_m(e, x)}^\chi(y) \]

Note. The function \( s^n_m \) here differs, of course, from the function given the same name in theorem 4-4.3. Note, however, that \( s^n_m \) here is still computable (not merely \( \chi \)-computable) and does not depend on \( \chi \).

Universal programs for relative computability. Relativisation of the proof of theorem 5-1.2 gives immediately:

4.7. Theorem
For each \( n \), the universal function \( \psi^n_\chi \) for \( n \)-ary \( \chi \)-computable functions given by

\[ \psi^n_\chi(e, x) = \phi_{\psi^n_\chi(e)}^\chi(x) \]

is \( \chi \)-computable.

Remark. A careful examination of the full formal proof of theorem 5-1.2 would show that there is a URMO program \( Q_\chi^n \), independent of \( \chi \), that \( \chi \)-computes \( \psi^n_\chi \) for any \( \chi \).

\( \chi \)-recursive and \( \chi \)-r.e. sets. The relativised notions of recursive and r.e. sets are given by:

4.8. Definition
Let \( A \) be a set
(a) \( A \) is \( \chi \)-recursive (or recursive in \( \chi \)) if \( c_A \) is \( \chi \)-computable.
(b) \( A \) is \( \chi \)-r.e. (or r.e. in \( \chi \)) if the partial characteristic function

\[ f(x) = \begin{cases} \frac{1}{0} & \text{if } x \in A, \\
\text{undefined} & \text{if } x \notin A, \end{cases} \]

is \( \chi \)-computable.
9 Reducibility and degrees

The following selection of basic results about $\chi$-recursive and $\chi$-r.e. sets is proved by the addition of the prefix $\chi$- at the appropriate places in the proofs of the corresponding unrelativised results in chapter 7:

4.9. Theorem
(a) For any set $A$, $A$ is $\chi$-recursive iff $A$ and $\bar{A}$ are $\chi$-r.e.
(b) For any set $A$, the following are equivalent
   (i) $A$ is $\chi$-r.e.,
   (ii) $A = W_n^\chi$ for some $m$,
   (iii) $A = E_n^\chi$ for some $m$,
   (iv) $A = \emptyset$ or $A$ is the range of a total $\chi$-computable function,
   (v) for some $\chi$-decidable predicate $R(x, y)$,
      \[ x \in A \iff \exists y R(x, y) \]
      ($R$ is $\chi$-decidable if its characteristic function is $\chi$-computable).
(c) Let $K^\chi = \{x : x \in W_n^\chi\}$; then $K^\chi$ is $\chi$-r.e. but not $\chi$-recursive.

Computability relative to a set For any set $A$, we define computability relative to $A$ (or just $A$-computability) to mean computability relative to $\bar{c}_A$, the characteristic function of $A$. Thus we write

- $P^\chi$ for $P^{\bar{c}_A}$ (if $P$ is a URM0 program),
- $\emptyset^\chi$ for $\emptyset^{\bar{c}_A}$,
- $\phi^\chi_m$ for $\phi^{\bar{c}_A}_m$,
- $W^\chi_m$ for $W^{\bar{c}_A}_m$,
- $E^\chi_m$ for $E^{\bar{c}_A}_m$,
- $K^\chi$ for $K^{\bar{c}_A}$,
- $A$-recursive for $c_A$-recursive,
- $\chi$-r.e. for $c_A$-r.e.,
- etc.

In the next section we shall define Turing reducibility in terms of computability relative to a set. For a set $A$, we can summarise the basic idea that we have presented in this section, in a nutshell, as follows: $A$-computability is computability for anyone who knows all about $A$. To be a little more precise, we should expand this to: for anyone who can answer any question of the form `$x \in A$?'. This excludes knowledge of 'infinite' facts about $A$, such as whether $A$ has infinitely many even members.

4.10. Exercises
1. Let $\chi$, $\psi$ be total unary functions, and suppose that $\phi^\chi_0$ is total. Is $\phi^\psi_0$ necessarily total?
2. Suppose that $X_1, X_2, \ldots, X_k$ are total unary functions. Define $\mathcal{R}^{X_1, X_2, \ldots, X_k}$ to be the smallest class of functions containing the basic functions and $X_1, \ldots, X_k$, and closed under substitutions, recursion and minimalisation. Formulate a definition of the set $\mathcal{E}^{X_1, X_2, \ldots, X_k}$ of functions computable relative to $X_1, \ldots, X_k$ such that $\mathcal{E}^{X_1, X_2, \ldots, X_k} = \mathcal{R}^{X_1, X_2, \ldots, X_k}$. (Hint: Either define a machine having $k$ oracles, or find a single unary function $\chi$ such that $\mathcal{R}^{X_1, X_2, \ldots, X_k} = \mathcal{E}_\chi$.)
3. Provide a full formal proof of theorem 4.3(c): if $\chi$ is computable, then $\emptyset = \emptyset^\chi$.
4. Show that there are a total computable function $k$ (independent of $\chi$) such that $W^{\chi}_{k(a, c)} = W^a_2 \cup W^c_2$ for all indices $a, b$.
5. Verify theorem 4.9.
   (a) Show that for any r.e. set $B$, there is an index $e$ such that $B = W^\emptyset_e$.
   (b) Show that if $A$ is r.e., then $W^\emptyset_e$ is r.e. for all $e$.
   (c) Show that if $A$ is r.e., then $K^A$ is r.e. but not r.e.
7. Let $A, B, C$ be sets. Prove that
   (a) if $A$ is $B$-recursive and $B$ is $C$-recursive, then $A$ is $C$-recursive,
   (b) if $A$ is $B$-r.e. and $B$ is $C$-recursive, then $A$ is $C$-r.e.,
   (c) if $A$ is $B$-recursive and $B$ is $C$-r.e., then $A$ is not necessarily $C$-r.e.
8. (Relativisation of theorem 1.6.) Let $A$ be any set. Show that for any set $B$,
   \[ B = A \text{-r.e. } \iff B \subseteq K^A. \]
9. Show that there is a single number $d$ such that $K^A = W^\emptyset_d$ for all sets $A$.
10. (a) We say that a set $A$ is $\chi$-simple if (i) $A$ is $\chi$-r.e., (ii) $\bar{A}$ is infinite, (iii) $\bar{A}$ contains no infinite $\chi$-r.e. subset. Show that there is a $\chi$-simple set.
    (b) Formulate the definition of a $\chi$-creative set. Show that a $\chi$-simple set is not $\chi$-creative.
5. Turing reducibility and Turing degrees

Using relative computability we make the following definitions:

5.1. Definitions
(a) The set $A$ is Turing reducible (or just $T$-reducible) to the set $B$ if $A$ is $B$-recursive (equivalently, if $e_A$ is $B$-computable). This is written $A \leq_T B$.
(b) The sets $A$, $B$ are Turing equivalent (or $T$-equivalent) if $A \leq_T B$ and $B \leq_T A$. (The use of the word equivalent is justified in theorem 5.2(b) below.) We write this $A \equiv_T B$.

Let us consider informally the meaning of Turing reducibility. Suppose that $A \leq_T B$ and that $P$ is a URMO program that computes $e_A$ relative to $B$. Then for any $x$, $P^B(x)$ converges and

$$P^B(x) = 1 \text{ if } x \in A,$$
$$P^B(x) = 1 \text{ if } x \notin A.$$ 

During any completed computation $P^B(x)$ there will have been a finite number of requests to the oracle for a value $e_B(n)$ of $e_B$ as dictated by $P$ and the progress of the computation. These requests amount to a finite number of questions of the form 'Is $n$ in $B$?'. So for any $x$, $x \in A$? is settled in a mechanical way by answering a finite number of questions about $B$. Thus we see that Turing reducibility accords with the informal notion of reducibility discussed at the beginning of §4.

Some of the basic properties of the relations $\leq_T$ and $\equiv_T$ are given in the next theorem.

5.2. Theorem
(a) $\leq_T$ is reflexive and transitive,
(b) $\equiv_T$ is an equivalence relation,
(c) If $A \leq_T B$ then $A \equiv_T B$,
(d) $A \equiv_T A$ for all $A$,
(e) If $A$ is recursive, then $A \leq_T B$ for all $B$,
(f) If $A$ is recursive and $B \leq_T A$ then $B$ is recursive,
(g) If $A$ is r.e. then $A \leq_T K$.

Proof.
(a) and (b) follow immediately from the observation that $A \leq_T B \iff \forall x e^A = e^B$ (by theorem 4.3(a), (e))
and hence
$A \equiv_T B \iff e^A = e^B$.

5.3. Definition
A set $A$ is $T$-complete if $A$ is r.e. and $B \leq_T A$ for every r.e. set $B$.

The name Turing degree is given to any equivalence class of sets under the relation $\equiv_T$: again, we think of a degree as a collection of sets all having the same degree of difficulty.

5.4. Definitions
(a) Let $A$ be a set; the equivalence class
d$_T(A) = \{ B : B \equiv_T A \}$
is called the Turing degree of $A$, abbreviated the $T$-degree of $A$.
(b) Any $T$-degree containing a recursive set is called a recursive $T$-degree.
(c) Any $T$-degree containing an r.e. set is called an r.e. $T$-degree.

The notions of Turing reducibility and Turing degree are widely accepted as the most basic among all other similar notions. Hence the term reducible without qualification is often used to mean Turing reducible; similarly, Turing degrees are often referred to merely as degrees, or degrees of unsolvability. We shall adopt this practice in the remainder of our chapter. As before, the letters $a$, $b$, $c$, etc. are used for degrees.

The relation $\leq_T$ on sets induces a partial ordering on degrees, as with $\leq_m$: 
5.5. Definition
Let \( a, b \) be degrees.
(a) \( a \equiv b \) if for some (equivalently, for all) \( A \in a \) and \( B \in b \), \( A \equiv_T B \);
(b) \( a < b \) if \( a \not\equiv b \) and \( a \neq b \).
(We leave it as an easy exercise for the reader to verify that \( < \) is a partial ordering on degrees (cf. theorem 2.6).)

We can reformulate much of theorem 5.2 in terms of degrees as follows:

5.6. Theorem
(a) There is a single recursive degree, which is denoted \( 0 \); \( 0 \) consists of all the recursive sets, and is the unique minimum degree.
(b) Let \( 0' \) denote the degree of \( K \); then \( 0 < 0' \) and \( 0' \) is a maximum among all r.e. degrees.
(c) For any sets \( A, B \)
(i) \( d_{lm}(A) \leq d_{lm}(A) \),
(ii) if \( d_{lm}(A) \leq d_{lm}(B) \), then \( d_{lm}(A) \leq d_{lm}(B) \).

Proof.
(a) This is immediate from theorem 5.2(e) and (f).
(b) From (a) \( 0 \equiv 0' \); and \( 0 \neq 0' \) since \( K \) is not recursive. By theorem 5.2(g), if \( a \) is any r.e. degree, \( a \equiv 0' \).
(c) Immediate from theorem 5.2(c).

There are two fundamental features of the structure of Turing degrees under their partial ordering that we should now mention.

The jump operation
We have seen that the step from recursive sets to T-complete sets such as \( K \) is a definite increase in degree of difficulty, expressed in the language of T-degrees by writing \( 0 < 0' \). We now show that for any degree \( a \) there is a corresponding step or jump to a higher degree \( a' \), known as the jump of \( a \). This is defined using the set \( K^a = \{ x : x \in W^a \} \) (for any set \( A \in a \)); but first we need the following theorem.

5.7. Theorem
Let \( A, B \) be any sets.
(a) (i) \( K^A \) is A-r.e.,
(ii) if \( B \) is A-r.e., then \( B \leq_T K^A \).
(b) If \( A \) is recursive then \( K^A \equiv_T K \).
(c) \( A <_T K^A \).
(d) (i) If \( A \leq_T B \) then \( K^A \leq_T K^B \),
(ii) if \( A =_T B \) then \( K^A =_T K^B \).

Proof.
(a) (i) is given by theorem 4.9(c); for (ii), a straightforward relativisation of theorem 1.6 (using the relativised s-m-n theorem) shows that if \( B \) is A-r.e. then \( B \equiv_a K^A \).
(b) Clearly \( K \leq_T K^A \), since \( K \) is A-r.e. for any \( A \); on the other hand, if \( A \) is recursive then the A-computable partial characteristic function of \( K^A \) is actually computable (theorem 4.3(c)); hence \( K^A \) is r.e. Thus \( K^A \equiv_T K \).
(c) \( A <_T K^A \) is given by (a)(ii); \( A \equiv_T K^A \) is given by theorem 4.9(c).
(d) (i) If \( A \leq_T B \), then since \( K^A \) is A-r.e. it is also B-r.e. (see exercise 4.10(7b)). Hence \( K^A \equiv_T K^B \) by (a)(ii).
(ii) follows immediately from (i).

Part (a) of this theorem tells us that \( K^A \) is what we would call a T-complete A-r.e. set; it is sometimes called the completion of \( A \), but usually it is called the jump of \( A \) and denoted \( A' \).

Notice that for any \( A \in 0 \), the degree of \( K^A \) is \( 0' \) (by (b) of the above theorem). This leads to the following definition of the jump operator on degrees.

5.8. Definition
For any degree \( a \), the jump of \( a \), denoted \( a' \), is the degree of \( K^A \) for any \( A \in a \).

Remarks
1. Theorem 5.7(d) tells us that this is a valid definition because the degree of \( K^A \) is the same for every \( A \in a \).
2. By theorem 5.7(b) the new definition of \( 0' \) here as the jump of \( 0 \) accords with our earlier definition of \( 0' \) as the degree of \( K \) (theorem 5.6).

We can immediately write down the basic properties of the jump operator:

5.9. Theorem
For any degrees \( a, b \)
5.12. **Theorem**

Any non-recursive r.e. degree contains a simple set.

*Proof (sketch).* Let \( B \) be an r.e. set that is not recursive, and let \( B = \text{Ran}(f) \) where \( f \) is a total injective computable function (exercise 7.2.18(7)). Let \( A \) be the set given by

\[
A = \{ x : \exists y ( y > x \text{ and } f(y) < f(x) ) \}.
\]

In exercise 7.4.4(2) we gave the hint for showing that \( A \) is simple. We leave the proof that \( A \equiv_T B \) as an exercise (exercise 5.2.1(6) below).

This theorem underlines the difference between m-degrees and T-degrees, since it shows that \( 0' \), unlike \( 0_m \), contains many r.e. sets that are not m-complete.

The breakthrough on Post's problem came in 1956 when Friedberg and Muchnik independently proved:

5.13. **Theorem**

There are r.e. sets \( A, B \) such that \( A \equiv_T B \) and \( B \not\equiv_T A \). Hence, if \( a, b \) are \( d_1(A), d_2(B) \) respectively, \( a \not\leq b \) and \( b \not\leq a \), and thus \( 0 < a < 0' \) and \( 0 < b < 0' \).

(Degrees \( a, b \) such that \( a \leq b \) and \( b \leq a \) are called incomparable degrees; this is written \( a \parallel b \).)

For a proof of the Friedberg–Muchnik theorem, which is well beyond the scope of this book, we refer the reader to books such as Rogers [1967] or Shoenfield [1971]. Friedberg and Muchnik used a new technique known as the priority method, which opened the way to the discovery of the complex nature of the structure of the Turing-degrees.

There are many results about degrees that, like the Friedberg–Muchnik theorem, are easy to formulate but difficult to prove. We give below a sample of these, to illustrate the complexity of the T-degrees.

5.14. **Theorem**

For any r.e. degree \( a > 0 \), there is an r.e. degree \( b \) such that \( b \parallel a \).

5.15. **Sacks' Density theorem**

For any r.e. degrees \( a < b \) there is an r.e. degree \( c \) with \( a < c < b \).

5.16. **Sacks' Splitting theorem**

For any r.e. degree \( a > 0 \) there are r.e. degrees \( b, c \) such that \( b < a, c < a \) and \( a = b \cup c \) (hence \( b \parallel c \)).
5.17. **Theorem** (Lachlan, Yates)
(a) There are r.e. degrees \(a, b > 0\) such that 0 is the greatest lower bound of \(a\) and \(b\).
(b) There are r.e. degrees \(a, b\) having no greatest lower bound (either among all degrees or among r.e. degrees).

Turning to non r.e. degrees, a surprising result is

5.18. **Theorem** (Shoenfield)
There is a non-r.e. degree \(a < 0\).

A minimal degree is a degree \(m > 0\) such that there is no degree \(a\) with \(0 < a < m\). By Sacks' Density theorem there can be no minimal r.e. degree. However, Spector proved:

5.19. **Theorem**
There is a minimal degree.

For proofs of these and other results about degrees we refer the reader again to the books of Rogers and Shoenfield. The article by Simpson [1977] gives a very readable survey of more recent results that are not included in these books.

**T-degrees and m-degrees** Often results about T-degrees give information about the structure of the m-degrees almost immediately, via theorem 5.6(c). We illustrate with

5.20. **Corollary** (to theorem 5.14)
For any r.e. m-degree \(a \geq m\), there is an r.e. m-degree \(b\) such that \(b \nleq a\).

**Proof.** Let \(a \in \mathbb{A}; \ a\) is r.e. so by theorem 5.14 take an r.e. T-degree \(c\) such that \(d_T(A) \leq c\). Let \(B\) be an r.e. set in \(c\) and let \(b = d_m(B)\). Then if \(a \leq m\) or \(b \leq a\), by theorem 5.6(c) we have \(d_T(A) \leq c\) or \(c \leq d_T(A)\), contradicting \(d_T(A) \leq c\). Hence \(a \nleq b\). □

**Other reducibilities** There are other notions of reducibility that lie between the restricted notion of m-reducibility and the broader T-reducibility. The book of Rogers [1967] provides a full and detailed discussion of these.
10

Effective operations on partial functions

Once we have studied effectively computable operations on numbers it is
natural to ask whether there is a comparable notion for operations on
functions. The essential difference between functions and numbers as
basic objects is that functions are usually infinite rather than finite. With
this in mind, in §1 of this chapter we discuss the features we might
reasonably expect of an effective operator on partial functions; this leads
to the formulation of the definition of recursive operators on partial
functions.

In §2 we shall see that there is a close connection between recursive
operators and those effective operations on computable functions that we
discussed in Chapter 5 §3. In §3 we prove the important fixed point
theorem for recursive operators known as the first Recursion theorem.
The final part of this chapter provides a discussion of some of the
applications of this theorem in computability and the theory of pro-
gramming.

1. Recursive operators

Let us denote by \( S_n \) (\( n \geq 1 \)) the class of all partial functions from
\( \mathbb{N}^n \) to \( \mathbb{N} \). We use the word operator to describe a function \( \Phi : S_n \to S_n \); the
letters \( \phi, \psi, \ldots \) will invariably denote operators in this chapter. We shall
confine our attention to totally defined operators \( \Phi : S_n \to S_n \); i.e. such
that the domain of \( \Phi \) is the whole of \( S_n \).

The chief problem when trying to formulate the idea of a computable
(or effective) operator \( \Phi : S_1 \to S_1 \), say, is that both an 'input' function \( f \)
and the 'output' function \( \Phi(f) \) are likely to be infinite objects, and hence
incapable of being given in a finite time. Yet our intuition about effective
processes is that in some sense they should be completed within a finite
time.

To see how this problem can be overcome, consider the following
operators from \( S_1 \) to \( S_1 \):

\begin{enumerate}
\item \( \Phi_1(f) = 2f \).
\item \( \Phi_2(f) = g \) where \( g(x) = \sum_{y \leq x} f(y) \).
\end{enumerate}

These operators are certainly down to earth and explicit. Intuitively we
might regard them as effective operators; but why? Let \( f \in S_1 \) and let
\( g = \Phi_2(f) \); notice that any particular value \( g(k) \) (if defined) can be
computed in finite time from the single value \( f(k) \) of \( f \); if we set
\( g = \Phi_2(f) \), then to calculate \( g(k) \) (if defined) we need to know the finite
number of values \( f(0), f(1), \ldots, f(k) \). Thus in both cases any defined
value of the output function \( \Phi_1(f) \) or \( \Phi_2(f) \) can be effectively computed
in a finite time using only a finite part of the input function \( f \). This is
essentially the definition of a recursive operator given below.

One consequence of the definition will be the following: suppose that
\( \Phi_1(f)(x) = y \) is calculated using only a finite part \( \theta \) of \( f \); then if \( g \) is any
other function having \( \theta \) as a finite part we must expect that \( \Phi_2(g)(x) = y \)
also.

To frame our definition precisely there are some technical consider-
tations. First, let us agree that by a 'finite part' of a function \( f \) we mean a
finite function \( \theta \) extended by \( \delta \). (We say that \( \theta \) is a finite function if its
domain is a finite set.) For convenience we adopt the convention

\[ \theta \text{ always denotes a finite function in this chapter}. \]

The above discussion shows that the definition of recursive operator
will involve effective calculations with finite functions. We make
this precise by coding each finite function \( \theta \) by a number \( \hat{\theta} \) and using ordinary
computability. A suitable coding for our purposes is defined as follows:

\begin{align*}
\text{suppose that } \theta & \in S_n. \text{ The } n\text{-tuple } x = (x_1, x_2, \ldots, x_n) \text{ is coded by the number } \\
& = p_1^{x_1} p_2^{x_2} \cdots p_n^{x_n}, \text{ then define the code } \hat{\theta} \text{ for } \theta \text{ by }
\end{align*}

\[ \hat{\theta} = \prod_{x \in \text{Dom}(\theta)} p_{\theta(x)}^{\theta(x)+1} \quad \text{provided that } \text{Dom}(\theta) \neq \emptyset, \]

\[ \hat{\theta} = 0 \quad \text{if } \text{Dom}(\theta) = \emptyset \]

(in which case \( \theta = \delta \)).

There is a simple effective procedure to decide for any number \( \hat{\theta} \)
whether \( \hat{\theta} = \hat{\phi} \) for some finite function \( \phi \); and if so, to decide whether a given \( x \)
belongs to \( \text{Dom}(\phi) \), and calculate \( \phi(x) \) if it does.

Now we have our definition:

1.1. Definition

Let \( \Phi : S_n \to S_n \). Then \( \Phi \) is a recursive operator if there is a
computable function \( \phi(x, z) \) such that for all \( f \in S_n \) and \( x \in \mathbb{N}^n, y \in \mathbb{N} \)

\[ \phi(x, z) \]
The use of the term continuous to describe the property 1.3(a) is justified informally as follows. Suppose that \( \Phi : \mathcal{F}_1 \rightarrow \mathcal{F}_1 \) satisfies 1.3(a) and \( f \in \mathcal{F}_1 \). Then given any \( x_1, \ldots, x_i \) for which \( \Phi(f)(x_i) \) \( (1 \leq i \leq k) \) are defined, using 1.3(a) we can obtain a finite \( \delta \subseteq f \) such that \( \Phi(\delta)(x_i) = \Phi(f)(x_i) \) \( (1 \leq i \leq k) \). Thus, whenever \( \delta \supseteq \delta \), by 1.3(a) again, we have \( \delta(x) = \Phi(f)(x) \) \( (1 \leq i \leq k) \), i.e. if \( g \) is 'near' to \( f \) (in the sense that they agree on the finite set \( \text{Dom}(\delta) \)) then \( \Phi(g) \) is 'near' to \( \Phi(f) \) (in the sense that they agree on the finite set \( x_1, \ldots, x_k \)). Thus, informally, \( \Phi \) is continuous.

The continuity property 1.3(a) specifies that a value \( \Phi(f)(x) \) is determined (if at all) by a finite amount of positive information about \( f \). This means information asserting that \( f \) is defined at certain points and takes certain values there, as opposed to negative information that would indicate points where \( f \) is not defined. Using this idea the term continuous can be rigorously justified as follows.

The positive information topology\(^1\) on \( \mathbb{F}_m \) is defined by taking as base of open neighbourhoods sets of the form

\[ U_\theta = \{ f : \delta \subseteq f \} \quad (\theta \in \mathbb{F}_m, \text{finite}) \]

Thus \( f \) belongs to \( U_\theta \) if \( \theta \) is correct positive information about \( f \). It is then an easy exercise to see that an operator is continuous with respect to the positive information topology precisely when it possesses property 1.3(a).

The following characterisation of recursive operators using continuity will make it easy to establish recursiveness of various operators.

1.5. **Theorem**

Let \( \Phi : \mathbb{F}_m \rightarrow \mathbb{F}_n \) be an operator. Then \( \Phi \) is a recursive operator iff

(a) \( \Phi \) is continuous,

(b) the function \( \phi(z, x) \) given by

\[ \begin{align*}
\phi(\delta, x) &= \Phi(\delta) \quad \text{for } \delta \in \mathbb{F}_m, \\
\phi(z, x) &= \text{undefined} \quad \text{for all other } z.
\end{align*} \]

is computable.

**Proof.** Suppose that \( \Phi \) is recursive with computable function \( \phi \), such that

\[ \Phi(f)(x) = y \text{ if } \exists \delta : \delta \subseteq f \text{ and } \phi(\delta, x) = y. \]

1. The reader unfamiliar with topology will lose nothing in further development by omitting this paragraph.
Then taking $\phi$ as given in the theorem, we have
\[ \phi(\hat{\theta}, x) = y \iff \exists \theta (\theta \equiv \theta \text{ and } \phi(\hat{\theta}, x) = y); \]
the relation on the right is partially decidable, so $\phi$ is computable by theorem 6-6.13.

Conversely, suppose that conditions (a) and (b) of the theorem hold; then
\[ \Phi(f)(x) = y \iff \exists \theta (\theta \equiv f \text{ and } \Phi(\theta)(x) = y) \text{ (by (a))} \]
\[ \iff \exists \theta (\theta \equiv f \text{ and } \phi(\hat{\theta}, x) = y) \text{ (by (b))}, \]
whence $\Phi$ is a recursive operator. \( \square \)

This theorem enables us to show quite easily that the following operators are all recursive:

1.6. **Examples**

(a) (The diagonalisation operator) $\Phi(f)(x) = f(x, x)$ ($f \in \mathcal{F}_2$). $\Phi$ is obviously continuous, and $\phi(\hat{\theta}, x) = \theta(x, x)$ is computable.

(b) $\Phi(f)(x) = \sum_{f(y)} f(x) \text{ (if } f \in \mathcal{F}_1)$

This is the second example discussed at the beginning of this section. We saw there that $\Phi$ is continuous, and clearly $\phi(\hat{\theta}, x) = \sum_{f(y)} \theta(y)$ is computable.

(c) Let $g \in \mathcal{F}_1$ be computable. Define $\Phi: \mathcal{F}_n \to \mathcal{F}_n$ by $\Phi(f) = g \circ f$. Obviously $\Phi$ is continuous, and $\phi(\hat{\theta}, x) = g(\theta(x, x))$ is computable.

(d) (The Ackermann operator) Let $\Phi: \mathcal{F}_2 \to \mathcal{F}_2$ be given by
\[ \Phi(f)(0, y) = y + 1, \]
\[ \Phi(f)(x + 1, 0) = f(x, 1), \]
\[ \Phi(f)(x + 1, y + 1) = f(x, f(x, y + 1)). \]

To see that $\Phi$ is continuous, note that $\Phi(f)(x, y)$ depends on at most two particular values of $f$. For recursiveness, it is immediate by Church's thesis that the function $\phi$ given by
\[ \phi(\hat{\theta}, 0, y) = y + 1 \]
\[ \phi(\hat{\theta}, x + 1, 0) = \theta(x, 1) \]
\[ \phi(\hat{\theta}, x + 1, y + 1) = \theta(x, \theta(x + 1, y)) \]
is computable.

(e) (The $\mu$-operator.) Consider $\Phi: \mathcal{F}_n \to \mathcal{F}_n$, given by $\Phi(f)(x) = \mu y (f(x, y) = 0)$. It is immediate that this operator is continuous, and that the function $\phi$ given by
\[ \phi(\hat{\theta}, x) = \mu y (\theta(x, y) = 0) \]
is computable.

When the definition 1.1 of a recursive operator $\Phi: \mathcal{F}_n \to \mathcal{F}_n$ is extended to the case $n = 0$, we have what is called a recursive functional. The members of $\mathcal{F}_0$ are 0-ary functions; i.e., constants. Just as $\mathcal{F}_n$ ($n \geq 1$) includes the function that is defined nowhere, $\mathcal{F}_0$ includes the "undefined" constant, which is denoted by $\omega$. Thus $\mathcal{F}_0 = \mathbb{N} \cup \{\omega\}$, and an operator $\Phi: \mathcal{F}_n \to \mathcal{F}_n$ is a recursive functional if there is a computable function $\phi(x)$ such that for any $f \in \mathcal{F}_n$ and $y \in \mathbb{N}$:
\[ \Phi(f)(y) \iff \exists \theta (\theta \equiv f \text{ and } \phi(\hat{\theta}) = y). \]

We write $\Phi(f) = \omega$ if $\Phi(f)$ is undefined; this emphasises that $\Phi$ is still thought of as being a total operator.

We should point out that in some texts the term partial recursive functional $\mathcal{F}_n \to \mathcal{F}_n$ is used to describe recursive operators, including the case $n = 0$. In such contexts the word partial generally describes the kind of object being operated on rather than the domain of definition of the operation.

We shall not discuss here the extension of the ideas of this section to partially defined operators, and the corresponding partial recursive operators $\Phi: \mathcal{F}_m \to \mathcal{F}_n$. The reader is referred to Rogers [1967] for a full discussion of these and related matters.

1.7. **Exercises**

1. Show that the following operators are recursive.
   (a) $\Phi(f) = f^2$ ($f \in \mathcal{F}_1$),
   (b) $\Phi(f) = g$ ($f \in \mathcal{F}_1$), where $g$ is a fixed computable function in $\mathcal{F}_1$.
   (c) $\Phi(f) = f \circ g$ ($f \in \mathcal{F}_1$) where $g$ is a fixed computable function in $\mathcal{F}_n$.
   (d) Let $h \in \mathcal{F}_{n+1}$ be a fixed computable function; define
   \[ \Phi: \mathcal{F}_{n+1} \to \mathcal{F}_{n+1} \text{ by } \]
   \[ \Phi(f)(x, y) = f(x + 1, y + 1) \text{ if } h(x, y) \text{ is defined and } \neq 0, \]
   \[ \text{undefined otherwise} \]
   (The significance of this operator will be seen later.)

2. Prove that if $\Phi$ is a recursive operator and $f$ is computable then so is $\Phi(f)$.

3. Decide whether the following operators $\Phi: \mathcal{F}_1 \to \mathcal{F}_1$ are (i) monotonic, (ii) continuous, (iii) recursive.
   (a) $\Phi(f)(x) = \begin{cases} f(x) & \text{if } \text{Dom}(f) \text{ is finite,} \\ \text{undefined} & \text{if } \text{Dom}(f) \text{ is infinite.} \end{cases}$
(b) \( \Phi(f)(x) = \begin{cases} 0 & \text{if } f(x) \text{ is defined,} \\ \text{undefined} & \text{otherwise.} \end{cases} \)

(c) \( \Phi(f)(x) = \begin{cases} 0 & \text{if } f(x) \in K \\ 1 & \text{if } f(x) \text{ is defined,} \\ \text{undefined} & \text{otherwise.} \end{cases} \)

(d) \( \Phi(f)(x) = \begin{cases} \text{undefined} & \text{if } \text{Dom}(f) \text{ is finite,} \\ f(x) & \text{if } \text{Dom}(f) \text{ is infinite.} \end{cases} \)

4. Suppose that \( \Phi: \mathcal{F}_n \rightarrow \mathcal{F}_n \) and \( \Psi: \mathcal{F}_n \rightarrow \mathcal{F}_n \) are recursive operators. Prove that \( \Psi \circ \Phi: \mathcal{F}_n \rightarrow \mathcal{F}_n \) is recursive.

5. Show how to extend the definition of recursive operator to include operators \( \Phi: \mathcal{F}_n \times \mathcal{F}_n \times \ldots \times \mathcal{F}_n \rightarrow \mathcal{F}_n \) and prove appropriate versions of theorems 1.4 and 1.5 for your definition. Prove that the following operators are recursive:

(a) \( \Phi: \mathcal{F}_n \rightarrow \mathcal{F}_n \) given by \( \Phi(f, g) = f \circ g \) (cf. question 1c above);

(b) \( \Phi: \mathcal{F}_{n+1} \times \mathcal{F}_{n+1} \rightarrow \mathcal{F}_{n+1} \) given by

\[
\Phi(f, h)(x) = \begin{cases} 0 & \text{if } h(x, y) = 0; \\ f(x+1, y+1) & \text{if } h(x, y) \text{ is defined and is not 0,} \\ \text{undefined} & \text{otherwise.} \end{cases}
\]

(cf. 1d above).

6. (For those who know some topology.)

(a) Prove that an operator is continuous in the sense of definition 1.3(a) iff it is continuous in the positive information topology.

(b) Prove that the following are equivalent for \( V \subseteq \mathcal{F}_n \):

(i) \( V \) is open in the positive information topology,

(ii) \( f \in V \) iff \( \exists \theta \subseteq f \) and \( \theta \in V \).

7. Let \( \Phi: \mathcal{F}_n \rightarrow \mathcal{F}_n \) and \( \Psi: \mathcal{F}_n \rightarrow \mathcal{F}_n \) be continuous operators; prove that \( \Psi \circ \Phi: \mathcal{F}_n \rightarrow \mathcal{F}_n \) is continuous.

8. Let \( \mathcal{P}(n) \) denote the class of all subsets of \( \mathbb{N} \); formulate a definition of a recursive operator \( \Phi: \mathcal{P}(n) \rightarrow \mathcal{P}(n) \) that parallels the notion of a recursive operator from \( \mathcal{F}_1 \rightarrow \mathcal{F}_1 \). Frame and prove the theorems corresponding to theorems 1.4 and 1.5. (Hint. The question of membership \( x \in \Phi(A) \) should depend effectively on a finite amount of positive information about membership of the set \( A \).)

(Effective operators \( \mathcal{P}(n) \rightarrow \mathcal{P}(n) \) are called enumeration operators and are discussed in full in Rogers [1967].)

2. Effective operations on computable functions

In chapter 5 § 3 we considered that certain operations on computable functions should be called effective because they can be given by total computable functions acting on indices. For instance, in example 5.1.2 we saw that there is a total computable function \( g \) such that for all \( \varepsilon \in \mathbb{N}, \Phi^\varepsilon(\varepsilon)^m = \phi_{\varepsilon, \varepsilon} \).

We shall see in this section that any recursive operator \( \Phi \), when restricted to computable functions, yields an effective operation of this kind on indices. This is the first part of a theorem of Myhill and Shepherdson. They proved, moreover, that all such operations on indices of computable functions arise in this way.

We shall prove the two parts of the Myhill–Shepherdson result separately, taking the easier part first.

2.1. Theorem (Myhill–Shepherdson, part I)

Suppose that \( \Psi: \mathcal{F}_n \rightarrow \mathcal{F}_n \) is a recursive operator. Then there is a total computable function \( h \) such that

\[
\Psi(\phi^m_\varepsilon(x)) = \phi^m_{h(x)}(x) \quad (x \in \mathbb{N}).
\]

Proof. Let \( \psi \) be a computable function showing that \( \Psi \) is a recursive operator according to definition 1.1. Then for any \( \varepsilon \) we have

\[
\Psi(\phi^m_\varepsilon(x)) = y \Leftrightarrow \exists \theta \subseteq \phi^m_\varepsilon(x) \text{ and } \psi(\theta, x) = y.
\]

We shall show that the function \( g \) defined by

\[
g(\varepsilon, x) = \Psi(\phi^m_\varepsilon(x))
\]

is computable, by showing that the relation \( g(\varepsilon, x) = y \) is partially decidable. To this end, consider the relation \( R(\varepsilon, x, y) \) given by

\[
R(\varepsilon, x, y) = \exists \theta (\theta \subseteq \phi^m_\varepsilon(x) \text{ and } \psi(\theta, x) = y).
\]

Then \( R \) is partially decidable, with the following informal partial decision procedure:

1. Decide whether \( \varepsilon \neq \theta \) for some \( \theta \); if so obtain \( x_1, \ldots, x_n \in \mathbb{N}^n \) and \( y_1, \ldots, y_n \) such that \( \text{Dom}(\theta) = \{x_1, \ldots, x_n\} \) and \( \theta(x_i) = y_i \), for some \( 1 \leq i \leq k \);

2. For \( i = 1, \ldots, k \) compute \( \phi^{\psi(i)}(x_i) \); if, for \( 1 \leq i \leq k \), \( \phi^{\psi(i)}(x_i) \) is defined and equals \( y_i \), then

3. Compute \( \psi(\varepsilon, x) \) and if defined check whether it equals \( y \).

If \( R(\varepsilon, x, y) \) holds, this is a mechanical procedure that will tell us so in finite time, as required.
Since \( R(z, e, x, y) \) is partially decidable, so is the relation 
\[ \exists z \ R(z, e, x, y) \] 
(by theorem 6-6.5): but
\[ \exists z \ R(z, e, x, y) \iff \Psi(\phi_e^{(m)})(x) = y \]  
(from the definition of \( R \))
\[ \iff g(e, x) = y \]  
(from the definition of \( g \)).
Thus \( g(e, x) = y \) is partially decidable, so by theorem 6-6.13 \( g \) is computable.

Now the \( s-m-n \) theorem provides a total computable function \( h \) such that
\[ \phi_{h(e)}(x) = g(e, x) \]
\[ \iff \Psi(\phi_e^{(m)})(x), \]
from which we have \( \phi_{h(e)}^{(n)} = \Psi(\phi_e^{(m)}) \).

Notice that the function \( h \) given by this theorem for a recursive operator \( \Psi: \mathcal{F}_1 \to \mathcal{F}_1 \) is extensional in the following sense.

2.2. Definition
A total function \( h: \mathbb{N} \to \mathbb{N} \) is extensional if for all \( a, b \), if \( \phi_a = \phi_b \) then \( \phi_{h(a)} = \phi_{h(b)} \).

Now we can state the other half of Myhill and Shepherdson's result.

2.3. Theorem (Myhill–Shepherdson, part II)
Suppose that \( h \) is an extensional total computable function. Then there is a unique recursive operator \( \Psi \) such that \( \Psi(\phi_e) = \phi_{h(e)} \) for all \( e \).

Proof. At the heart of our proof lies an application of the Rice–Shapiro theorem (theorem 7-2.16).

Let \( h \) be an extensional total computable function. Then \( h \) defines an operator \( \Psi_h: \mathcal{C}_1 \to \mathcal{C}_1 \) by
\[ \Psi_h(\phi_e) = \phi_{h(e)} \]
\( \Psi_h \) is well defined since \( h \) is extensional. We have to show that there is a unique recursive operator \( \Psi: \mathcal{F}_1 \to \mathcal{F}_1 \) that extends \( \Psi_h \).

First note that \( \Psi_h(\theta) \) is defined for all finite \( \theta \), since finite functions are computable. Thus any recursive operator \( \Psi \) extending \( \Psi_h \), being continuous, must be defined by
\[ \Psi(f)(x) = y \iff \exists \theta(\theta \leq f \text{ and } \Psi_h(\theta)(x) = y). \]

So such a \( \Psi \), if it exists, is unique. To prove the theorem we must now show that
(i) (2.4) does define an operator \( \Psi \),
(ii) \( \Psi \) extends \( \Psi_h \),
(iii) \( \Psi \) is recursive.

We first use the Rice–Shapiro theorem to show that \( \Psi_h \) is continuous in the following sense: for computable functions \( f \)
\[ (2.5) \quad \Psi_f(x)(x) = y \iff \exists \theta(\theta \leq f \text{ and } \Psi(\theta)(x) = y). \]

To see this, fix \( x, y \) and let \( A = \{ f \in \mathcal{G}_1 : \Psi_f(x)(x) = y \} \). Then the set \( A = \{ e : \phi_e \in \mathcal{C}_1 : \Psi_e(\phi_e(x)) = y \} \) is r.e., so by the Rice–Shapiro theorem, if \( f \) is computable then
\[ f \in A \iff \exists \theta(\theta \leq f \text{ and } \theta \in \mathcal{C}_1), \]
which is precisely (2.5).

Now we establish (ii), (iii) above.
(i) Let \( f \) be any partial function; we must show that for any \( x, (2.4) \) defines \( \Psi(f)(x) \) uniquely (if at all). Suppose then that \( \theta_1, \theta_2 \leq f \) and \( \Psi_1(\theta_1)(x) = y_1 \) and \( \Psi_2(\theta_2)(x) = y_2 \). Take a finite function \( \theta = \theta_1 \circ \theta_2 \) (say), \( \theta = f \circ \operatorname{Dom}(\theta_1) \circ \operatorname{Dom}(\theta_2) \) (by (2.5)).
\[ y_1 = \Psi_1(\theta_1)(x) = \Psi_2(\theta_2)(x) = \Psi(\theta)(x) = y_2. \]

Thus (2.4) defines an operator \( \Psi \) unambiguously.

(ii) This is immediate from (2.5) and the definition (2.4).

(iii) We show that \( \Psi \) satisfies the conditions of theorem 1.5. Clearly \( \Psi \) is continuous, from the definition. For the other condition we must show that the function \( \psi \) given by
\[ \psi(\theta, x) = \Psi(\theta)(x), \]
\[ \psi(\theta, x) \text{ is undefined if } x \neq x, \]
is computable. Now it is easily seen by using Church's thesis that there is a computable function \( e \) such that for any finite function \( \theta \), \( e(\theta) \) is an index for \( \theta \); i.e., \( \theta = \phi_{e(\theta)} \). Thus
\[ \psi(\theta, x) = \Psi(\phi_{e(\theta)}(x)) = \phi_{h(e(\theta))}(x), \]
so \( \psi \) is computable, since \( h \) and \( e \) are. Hence \( \Psi \) is a recursive operator.

Remarks
1. The proof of theorem 2.3 actually shows that for any extensional computable \( h \) there is a unique continuous operator \( \Psi: \mathcal{F}_1 \to \mathcal{F}_1 \) such that \( \Psi(\phi_e) = \phi_{h(e)} \) for all \( e \), and that this operator is recursive.
2. Theorem 2.3 extends in a natural way to cover operators from \( \mathcal{F}_m \to \mathcal{F}_n \). The proof is almost identical, using the natural extension of the Rice–Shapiro theorem to subsets of \( \mathcal{F}_n \); see exercise 2.6(2) below.
2.6. **Exercises**

1. Suppose that \( \Phi, \Psi \) are recursive operators \( \mathcal{F}_1 \rightarrow \mathcal{F}_2 \); knowing that \( \Phi \circ \Psi \) is continuous (exercise 1.7(7)) use the two parts of the Myhill–Shepherdson theorem together with the first remark above to show that \( \Phi \circ \Psi \) is recursive.

2. State and prove a general version of theorem 2.3 for operators from \( \mathcal{F}_n \rightarrow \mathcal{F}_n \).

3. Formulate and prove versions of the Myhill–Shepherdson theorem (both parts) appropriate for the operators you have defined \( \sigma \) in exercise 1.7(5), \( \tau \) in exercise 1.7(8).

3. **The first Recursion theorem**

The first Recursion theorem of Kleene is a fixed point theorem for recursive operators, and is often referred to as the Fixed point theorem (of recursion theory). We shall see later that it is a very useful result.

3.1. **The first Recursion theorem (Kleene)**

Suppose that \( \Phi : \mathcal{F}_n \rightarrow \mathcal{F}_n \) is a recursive operator. Then there is a computable function \( f_\Phi \) that is the least fixed point of \( \Phi \); i.e.

(a) \( \Phi(f_\Phi) = f_\Phi \),

(b) if \( \Phi(g) = g \), then \( f_\Phi \leq g \).

Hence, if \( f_\Phi \) is total, it is the only fixed point of \( \Phi \).

**Proof.** We use the continuity and monotonicity of \( \Phi \) to construct the least fixed point \( f_\Phi \) as follows. Define a sequence of functions \( \{f_n\} \) \((n \in \mathbb{N})\) by

\[
f_0 = f_\varnothing \quad \text{(the function with empty domain)},
\]

\[
f_{n+1} = \Phi(f_n).
\]

Then \( f_0 = f_\varnothing \leq f_1 \); and if \( f_n \leq f_{n+1} \), by monotonicity we have that \( f_{n+1} = \Phi(f_n) \leq \Phi(f_{n+1}) = f_{n+1} \). Hence \( f_n \leq f_{n+1} \) for all \( n \). Now let

\[
f_\Phi = \bigcup_{n \in \mathbb{N}} f_n
\]

by which we mean

\[
f_\Phi(x) = y \text{ iff } \exists n \text{ such that } f_n(x) = y.
\]

We shall show that \( f_\Phi \) is a fixed point for \( \Phi \).

For all \( n \),

\[
f_n \leq f_\Phi
\]

hence

\[
f_{n+1} = \Phi(f_n) \leq \Phi(f_\Phi) = f_\Phi;
\]

thus

\[
f_\Phi \leq \Phi(f_\Phi).
\]

Conversely, suppose that \( \Phi(f_\Phi)(x) = y \); then there is finite \( \theta \leq f_\Phi \) such that \( \Phi(\theta)(x) = y \); take \( n \) such that \( \theta \leq f_n \); then by continuity \( \Phi(f_n)(x) = y \).

That is, \( f_{n+1}(x) = y \). Hence \( f_{n+1} = y \). Thus \( \Phi(f_\Phi) \leq f_\Phi \), and so \( \Phi(f_\Phi) = f_\Phi \) as required.

To see that \( f_\Phi \) is the least fixed point of \( \Phi \), suppose that \( \Phi(g) = g \); then clearly \( f_0 = f_\varnothing \leq g \) and by induction we see that \( f_n \leq g \) for all \( n \). Hence \( f_\Phi \leq g \), as required. Moreover, if \( f_\Phi \) is total, then \( f_\Phi = g \), so \( f_\Phi \) is the only fixed point of \( \Phi \).

Finally we show that \( f_\Phi \) is computable. Use theorem 2.1 to obtain a total computable function \( h \) such that for all \( e \)

\[
\Phi(e) = f_{h(e)}.
\]

Let \( e_0 \) be an index for \( f_0 \); define a computable function \( k \) by

\[
k(0) = e_0
\]

\[
k(n+1) = h(k(n)).
\]

Then \( f_n = f_{h(n)} \) for each \( n \); thus

\[
f_\Phi(x) = y \iff \exists n (f_{h(n)}(x) = y).
\]

The relation on the right hand side is partially decidable, and hence \( f_\Phi \) is computable. \( \square \)

**Remark.** The recursiveness of the operator \( \Phi \) was used in this proof only in showing that \( f_\Phi \) is computable. The first part of the proof shows that any continuous operator has a least fixed point.

We shall see in the following examples that a recursive operator may have many fixed points, and that the least fixed point is not necessarily a total function.

3.2. **Examples**

1. Let \( \Phi \) be the recursive operator given by

\[
\Phi(f)(0) = 1,
\]

\[
\Phi(f)(x + 1) = f(x + 2).
\]

Then the least fixed point is \( f_{\Phi}(0) = 1 \).

Other fixed points of \( \Phi \) take the form \( f(x + 1) = a \).
Recursion theorem. (In Kleene's equation calculus approach (see chapter 3 § 1), however, the first Recursion theorem is proved without the use of the \( \mu \)-operator, so closure under the \( \mu \)-operator is established by this example.)

We can see from the above examples why the first Recursion theorem is so called. The general idea of recursion is that of defining a function "in terms of itself". A simple instance of this is primitive recursion, discussed in chapter 2. We have seen more general forms of recursion in the definitions of Ackerman's function, and the function \( f_\phi \) in example 3.2(3) above.

We were able to see quite easily in chapter 2 that primitive recursive definitions are meaningful, but with more complex recursive definitions this is not so obvious; conceivably there are no functions satisfying the proposed definition. This is where the first Recursion theorem comes in. Very general kinds of definition by recursion are represented by an equation of the form
\[
(3.3) \quad f = \Phi(f)
\]
where \( \Phi \) is a recursive operator. The first Recursion theorem shows that such a definition is meaningful, there is even a computable function satisfying it. Since in mathematics we require that definitions define things uniquely, we can say that the recursive definition (3.3) defines the least fixed point of the operator \( \Phi \). Thus, according to the first Recursion theorem, the class of computable functions is closed under a very general form of definition by recursion.

3.4. Exercises

1. Find the least fixed point of the following operators:

   a. \( \Phi(f) = f \) \((f \in \mathcal{F})\);

   \( \Phi(f)(x) = \begin{cases} 
   0 & \text{if } x = 0, \\
   2x - 1 + f(x-1) & \text{if } x > 0;
   \end{cases} \)

   b. \( \Phi(f)(x) = f(x-1) \)

   \( \Phi(f)(x) = \begin{cases} 
   0 & \text{if } x = 0, \\
   f(x-1, f(x, y)) & \text{if } x > 0.
   \end{cases} \)

2. (McCarthy) Show that the function \( m(x) \) given by

   \( m(x) = \begin{cases} 
   91 & \text{if } x = 100, \\
   x - 10 & \text{otherwise};
   \end{cases} \)

   is the only fixed point of the recursive operator \( \Phi \) given by

   \( \Phi(f)(x) = \begin{cases} 
   f(f(x+11)) & \text{if } x \leq 100, \\
   x - 10 & \text{otherwise}.
   \end{cases} \)
3. Suppose that $\Phi$ and $\Psi$ are recursive operators $\mathcal{F}_1 \times \mathcal{F}_1 \rightarrow \mathcal{F}_1$ (in the sense you have defined in exercise 1.7(5)). Show that there is a least pair of functions $f, g$ such that

$$f = \Phi(f, g)$$
$$g = \Psi(f, g)$$

and $f, g$ are computable.

4. Suppose that $\Phi : \mathcal{F}_n \times \mathcal{F}_n \rightarrow \mathcal{F}_n$ is a recursive operator (in the sense you have defined in exercise 1.7(5)). For each $g \in \mathcal{F}_n$ let $\Phi_{\mathcal{F}_n} : \mathcal{F}_n \rightarrow \mathcal{F}_n$ be the operator given by $\Phi_{\mathcal{F}_n}(f) = \Phi(f, g)$. Show that the operator $\Psi_{\mathcal{F}_n}(f) = \text{least fixed point of } \Phi_{\mathcal{F}_n}$ is a recursive operator $\mathcal{F}_n \rightarrow \mathcal{F}_n$.

4. **An application to the semantics of programming languages**

We shall see in this section how the first Recursion theorem helps to resolve a problem in the semantics of computer programming languages—the area that deals with the question of giving meaning to programs. Our discussion is necessarily given in terms of a general and unspecified programming language, but this is adequate to explain the basic idea.

Suppose, then, that $L$ is a general programming language. The basic symbols of $L$ will have been chosen with a particular meaning in mind, so that the meaning of compound expressions built from them is also clear. We may then envisage a simple program for a function as follows. Suppose that $\tau(x)$ is an expression of $L$ such that whenever the variables $x$ are given particular values $a$, then $\tau(a)$ can be unambiguously evaluated according to the semantics of $L$. If we now take a function symbol $f$ of $L$ that does not occur in $\tau$, then

$$f(x) = \tau(f, x)$$

is a simple program for a function $f$, that has the obvious meaning: for any numbers $a$, $f(a)$ is obtained by evaluating the expression $\tau(a)$ according to the semantics of $L$.

Suppose now that $\tau$ is an expression in which the symbol $f$ does occur. We indicate this by writing $\tau(f, x)$. Then the program (4.1) becomes

$$f(x) = \tau(f, x).$$

This is now what is called a recursive program. Situations occur where this is the most natural and economical way to describe a function that we may desire the computer to compute. Yet the meaning of the 'program' (4.2) is not entirely clear. The fundamental problem with any recursive program is: how do we give it a precise meaning? It can hardly be called a program until this question is settled.

There are basically two approaches that provide an answer to this question:

(a) **The computational approach.** Here the function taken to be defined by a recursive program is given in terms of a method of computing it. This approach reflects the fact that the computer scientist needs to know not only what a program means, but also how to implement it.

(b) **The fixed point approach** gives a meaning to a recursive program by an application of the first Recursion theorem. The fixed point theory also resolves some problems raised by the computational approach, and actually shows that the two approaches may be viewed as complementary rather than competing.

Let us now briefly explain these two approaches and see how first Recursion theorem enters the picture.

**The computational approach** This is best described by giving some examples. Consider the recursive program

$$f(x) = \begin{cases} 1 & \text{if } x = 0, \\ 2f(x-1) & \text{if } x > 0. \end{cases}$$

(4.3)

(We are assuming that in $L$ we can formulate conditional expressions such as this.) Using the equation (4.3) we can formally evaluate the value $f(3)$, for instance, as follows:

$$f(3) = 2 \times f(2) = 2 \times 2 \times f(1) = 2 \times 2 \times 2 \times f(0) = 8.$$ 

Here we have made successive substitutions and simplifications using the formal equation (4.3). Hence if $f_1$ is the function deemed to be given by the program (4.3) we would have $f_1(3) = 8$.

With more complicated recursive programs there may be more than one way to use the formal equation $f(x) = \tau(f, x)$ in such an evaluation procedure. Consider, for instance, the recursive program

$$f(x, y) = \begin{cases} 1 & \text{if } x = 0, \\ f(x-1, f(x, y)) & \text{if } x > 0. \end{cases}$$

(4.4)

Suppose that we try formally to evaluate $f(1, 0)$. We have

$$f(1, 0) \approx f(0, f(1, 0)).$$

But now there is a choice of occurrences of $f$ for which to substitute...
Choosing the leftmost one and simplifying we have
\[ f(1, 0) = f(0, f(1, 0)) = 1 \] (since \( x = 0 \)).

If, on the other hand, we substitute for the rightmost occurrence of \( f \) each time, we obtain from (4.5)
\[
\begin{align*}
f(1, 0) &= f(0, f(1, 0)) = f(0, f(0, f(1, 0))) \\
&= f(0, f(0, f(0, f(1, 0)))) = \ldots
\end{align*}
\]
and in this case no 'value' for \( f(1, 0) \) emerges.

A computation rule is a rule \( R \) that specifies how to proceed when confronted with such a choice of possible substitutions during any formal evaluation procedure. The computational rules we considered for the recursive program (4.4) were 'leftmost' (LM) and 'rightmost' (RM).

There are many other possible rules. For any computation rule \( R \), and recursive program \( f(x) = \tau(f, x) \) we define the function \( f_{,R} \) by: \( f_{,R}(a) \) is the value obtained when \( f(a) \) is formally evaluated using the rule \( R \). If no value is thus obtained, \( f_{,R}(a) \) is undefined. (Thus for the recursive program (4.4) we have \( f_{,LM}(1, 0) = 1 \), and \( f_{,RM}(1, 0) \) is undefined.)

So we see that each computation rule gives a meaning to any recursive program (and, at the same time, a method of implementing it).

The above example demonstrates that different computation rules may give different meanings to any particular recursive program. The problem now for the computer scientist who chooses this computational approach is to decide which computation rule to choose. Moreover, for any rule \( R \), there is the question of determining in what sense, if any, the function \( f_{,R} \) satisfies the equation
\[
f(x) = \tau(f, x).
\]

The fixed point approach, using the first Recursion theorem, avoids these problems, and in fact sheds light on both of them, as we shall see.

The fixed point approach An expression \( \tau(f, x) \) of \( L \) gives rise to an operator \( \Phi : \mathcal{F}_n \to \mathcal{F}_n \) by setting
\[
\Phi(g)(x) = \tau(g, x)
\]
for any \( g \in \mathcal{F}_n \). Moreover, in most programming languages the finite and explicit nature of the expression \( \tau(f, x) \) ensures that \( \Phi \) is a recursive operator. The first Recursion theorem now tells us that \( \Phi \) has a computable least fixed point, which we may denote by \( f^* \). Thus we may define the function given by the program (4.2) as \( f^* \). This is quite reasonable, because \( f^* \) is computable, and moreover we know that \( f^*(x) = \tau(f, x) \), which is surely what the programmer intended.

There remains the matter of finding good practical procedures for implementing the program (4.2) with its meaning defined in this way. It can be shown that for any computation rule \( R \), \( f_{,R} \equiv f^* \); further, there are computation rules \( R \) for which \( f_{,R} = f^* \) for all \( \tau \). Any one of these may be chosen as a practical way of implementing recursive programs. Then we can say that the computational and fixed point approaches are complementary rather than opposed to each other: the fixed point approach, via the first Recursion theorem, gives theoretical justification for the particular computation rule chosen.

There are further advantages in adopting the fixed point approach (or a computation rule equivalent to it): there is a variety of useful induction techniques for proving correctness, equivalence, and other properties of recursive programs with fixed point semantics, and these can all be rigorously justified.

For a full discussion of this whole topic the reader is referred to the books of Bird [1976] and Manna [1974]. Here we have slightly simplified the framework within which the computer scientist works; in fact the fixed point \( f^* \) he chooses is least in a slightly different sense (but still given by a version of the first Recursion theorem).
The second Recursion theorem

The first Recursion theorem, together with the Myhill-Shepherdson theorem in the previous chapter, shows that for any extensional total computable function \( f \) there is a number \( n \) such that

\[ \phi_{f(n)} = \phi_n. \]

The second Recursion theorem says that there is such an \( n \) even when \( f \) is not extensional: we shall prove this in § 1 of this chapter.

This theorem (and its proof) may seem a little strange at first. Nevertheless it plays an important role in more advanced parts of the theory of computability. We shall use it in the promised proof of Myhill's theorem (theorem 9.3.5) and in the proof of the Speed-up theorem in the next chapter.

In § 1, after proving the simplest version of the second Recursion theorem, we describe some applications and interpretations of it: § 2 is devoted to a discussion of the idea underlying the proof of the theorem, and other matters, including the relationship between the two Recursion theorems. A more general version of the second Recursion theorem is proved in § 3, and is used to give the proof of Myhill's theorem.

1. The second Recursion theorem

First let us prove the theorem, and then see how we can understand it.

1.1. Theorem (The second Recursion theorem)

Let \( f \) be a total unary computable function; then there is a number \( n \) such that

\[ \phi_{f(n)} = \phi_n. \]

Proof. By the s-m-n theorem there is a total computable function \( s(x) \) such that for all \( x \)

\[ (*) \quad \phi_{f(s(x))}(y) = \phi_{s(x)}(y). \]

If \( \phi_n(x) \) is undefined, we mean the expression on the left of (*) to be undefined; alternatively, we can take the left of (*) to denote \( \psi_{s(x)}(\psi_{f(s(x))}(y)) \).

Now take any \( m \) such that \( s = \phi_m \); rewriting (*) we have

\[ \phi_{f(s(x))}(y) = \phi_{s(x)}(y). \]

Then, putting \( x = m \) and taking \( n = \phi_m(m) \) (which is defined, since \( \phi_m \) is total) we have

\[ \phi_{\phi_m(m)}(y) = \phi_N(y) \]

as required. \( \square \)

In spite of its appearance, for non-extensional functions \( f \) this is not a genuine fixed-point theorem: there is no induced mapping \( \phi_n \to \phi_{f(s)} \) of computable functions for which \( \phi_n \) could be called a fixed point. However, we do have an induced mapping \( f^* \) of programs given by

\[ f^*(P) = P_{f(s)}. \]

To expect a fixed point for \( f^* \) in general would be too much: this would be a program \( P \), such that \( f^*(P) \) and \( P_n \) are the same; i.e. \( f(s) = n \). But what theorem 1.1 says is that there is a program \( P_n \) such that \( f^*(P_n) \) and \( P_n \) have the same effect (when computing unary functions); i.e. \( \phi_{f(s)} = \phi_n \). Thus the second Recursion theorem is loosely called a pseudo-fixed point theorem, and for convenience, any number \( n \) such that \( \phi_{\phi_m(m)}(y) = \phi_n \) is called a fixed point or fixed point value for \( f \).

The second Recursion theorem is a result about indices for computable functions; it may be thought therefore that the proof rests on some special feature of the particular numbering of programs that has been chosen. Inspection of the proof shows, however, that we used only the s-m-n theorem and the computability of the universal function; neither of these results depends in any essential way on the details of our numbering. Moreover, theorem 1.1 can be used to establish the second Recursion theorem corresponding to any suitable numbering of programs; see exercise 1.10(9) below.

There are various ways in which theorem 1.1 can be generalised, although the idea underlying the proof remains the same. In exercise 1.10(7) we have the generalisation to \( k \)-ary functions for \( k > 1 \); in theorem 3.1 it is shown that a fixed point can be calculated effectively from various parameters that may be connected with \( f \).

We continue this section with some corollaries and applications of the second Recursion theorem.
1.2. Corollary

If \( f \) is a total computable function, there is a number \( n \) such that
\[ W_{(n)} = W_n \text{ and } E_{f(n)} = E_n. \]

Proof. If \( \phi_{f(n)} = \phi_n \), then \( W_{(n)} = W_n \) and \( E_{f(n)} = E_n. \)

1.3. Corollary

If \( f \) is a total computable function there are arbitrarily large numbers \( n \) such that \( \phi_{f(n)} = \phi_n \).

Proof. Pick any number \( k \); take a number \( e \) such that
\[ \phi_e \neq \phi_0, \phi_1, \ldots, \phi_k. \]

Define a function \( g \) by
\[ g(x) = \begin{cases} 
  e & \text{if } x \leq k, \\
  f(x) & \text{if } x > k.
\end{cases} \]

Then \( g \) is computable; let \( n \) be a fixed point for \( g \). If \( n \leq k \), then
\[ \phi_{f(n)} = \phi_e \neq \phi_n, \] a contradiction. Hence \( n > k \), so \( f(n) = g(n) \) and \( n \) is a fixed point for \( f \).

(In exercise 1.10(8) we shall indicate how the proof of theorem 1.1 can be modified to obtain an increasing effective enumeration of fixed points for \( f \).)

The following corollary summarises the way that the second Recursion theorem is often applied, in conjunction with the \( s-m-n \) theorem.

1.4. Corollary

Let \( f(x, y) \) be any computable function; then there is an index \( e \) such that
\[ \phi_e(y) = f(e, y). \]

Proof. Use the \( s-m-n \) theorem to obtain a total computable function \( s \) such that \( \phi_{s(n)}(y) = f(n, y) \); now apply theorem 1.1, taking \( e \) as a fixed point for \( s \).

As simple applications of this corollary, we have

1.5. Examples

(a) There is a number \( n \) such that \( \phi_n(x) = x^2 \), all \( x \): apply corollary 1.4 with \( f(m, x) = x^m \);

(b) there is a number \( n \) such that \( W_n = \{ n \} \): apply corollary 1.4 with
\[ f(x, y) = \begin{cases} 
  0 & \text{if } y = x, \\
  \text{undefined} & \text{otherwise},
\end{cases} \]

obtaining an index \( n \) such that \( \phi_e(y) \) is defined iff \( y = n \).

The second Recursion theorem received its name because, like the first Recursion theorem, it justifies certain very general definitions by recursion. Consider, for example, the following ‘definition’ of a function \( \phi_e \) in terms of a given total computable function \( f \):
\[ \phi_e = \phi_{f(e)}. \]

The function \( \phi_e \) is ‘defined’ effectively in terms of an algorithm for computing itself (coded by the number \( e \)). In spite of its appearance as a circular definition, we are told by the second Recursion theorem that there are computable functions \( \phi_e \) satisfying such a definition.

It is often useful in advanced computability theory to be able to make an even more general definition of a function \( \phi_e \) by recursion of the kind
\[ \phi_e(x) = g(e, x), \]

where \( g \) is a given total computable function. Again, think of \( \phi_e \) as ‘defined’ effectively in terms of a code for its own algorithm. Then the second Recursion theorem, in the guise of corollary 1.4, makes this kind of definition meaningful also. We shall use this fact in the Speed-up theorem in the next chapter.

We continue this section with some further straightforward, but sometimes surprising, consequences of theorem 1.1. First, we show how it can be used to give a simple proof of Rice’s theorem (6-1.7).

1.6. Theorem (Rice’s).

Suppose that \( \emptyset \subset \mathcal{A} \subset \mathcal{G} \), and let \( A = \{ x : \phi_e(x) \in \mathcal{A} \} \). Then \( A \) is not recursive.

Proof. Let \( a \in A \) and \( b \notin A \). If \( A \) is recursive, then the function \( f \) given by
\[ f(x) = \begin{cases} 
  a & \text{if } x \notin A, \\
  b & \text{if } x \in A,
\end{cases} \]
is computable. Further, \( f \) has the property that \( x \in A \Rightarrow f(x) \notin A \), for all \( x \).

On the other hand, by theorem 1.1, there is a number \( n \) such that \( \phi_{f(n)} = \phi_e \), so \( f(n) \notin A \Rightarrow n \in A \), a contradiction.
Another application of the second Recursion theorem shows, as promised in chapter 4 §2, that the ‘natural’ enumeration of computable functions without repetitions is not computable.

1.7. Theorem
Suppose that \( f \) is a total increasing function such that
(a) if \( m \neq n \), then \( \phi(n) \neq \phi(m) \),
(b) \( f(n) \) is the least index of the function \( \phi(n) \).

Then \( f \) is not computable.

Proof. Suppose that \( f \) satisfies the conditions of the theorem. By (a), \( f \) cannot be the identity function, so there must be a number \( k \) such that
\[
f(k) > k \quad (n \geq k),
\]
whence, by (b)
\[
\phi(f(k)) \neq \phi(k) \quad (n \geq k).
\]
On the other hand, if \( f \) is computable, then by corollary 1.3 there is a number \( n \geq k \) such that \( \phi(f(n)) = \phi(n) \), a contradiction. \( \square \)

Applications of the second Recursion theorem such as the following can be interpreted in anthropomorphic terms.

Let \( P \) be a program. We can regard the code number \( \gamma(P) \) as a description of \( P \). We could regard the program \( P \) as capable of self-reproduction if for all inputs \( x \) the computation \( P(x) \) gave as output its own description, \( \gamma(P) \). At first glance, it would seem difficult to construct a self-reproducing program \( P \), since to construct \( P \) we would need to know \( \gamma(P) \), and hence \( P \) itself, in advance. Nevertheless, the second Recursion theorem shows that there are such programs.

1.8. Theorem
There is a program \( P \) such that for all \( x \), \( P(x) \upharpoonright \gamma(P) \): i.e. \( P \) is self-reproducing.

Proof. If we write \( n \) for \( \gamma(P) \), the theorem says that there is a number \( n \) such that
\[
\phi_e(x) = n \quad (\text{for all } x).
\]
To establish this, simply apply corollary 1.4 to the function \( f(m, x) = m \).

We turn now to psychology. Recall the notation and terminology of chapter 5. There we defined a total computable function \( \sigma(e, x, t) \) that codes the state of the computation \( P_e(x) \) after \( t \) steps; \( \sigma(e, x, t) \) contains information about the contents of the registers and the number of the next instruction to be obeyed at stage \( t \). It is clear, then, that complete details of the first \( t \) steps of the computation \( P_e(x) \) are encoded by the number
\[
\sigma^*(e, x, t) = \prod_{i=1}^{t} p_i^{|\sigma(e, x, i)|}.
\]
Let us call the number \( \sigma^*(e, x, t) \) the code of the computation \( P_e(x) \) to \( t \) steps. Clearly \( \sigma^* \) is computable.

Suppose now that we are given a total computable function \( \phi \) and a program \( P \). By the \( \phi \)-analysis of the computation \( P(x) \) we mean the code of the computation \( P(x) \) to \( \phi(x) \) steps. We can call a program \( P \) \( \psi \)-introspective at \( x \) if \( P(x) \) converges and gives as output its own \( \psi \)-analysis; we call \( P \) totally \( \psi \)-introspective if it is \( \psi \)-introspective at all \( x \).

1.9. Theorem
There is a program \( P \) that is totally \( \psi \)-introspective.

Proof. Simply apply corollary 1.4 to the computable function \( f(x, x, \phi(x)) \), obtaining a number \( n \) such that
\[
\phi_e(x) = f(n, x) = \text{the } \psi \text{-analysis of } P_e(x).
\]

We close this section with a tale in which the second Recursion theorem appears in military dress.

We are at war. An operation is mounted to sabotage the enemy's central computer facility. Our special agents have penetrated the enemy defences and found a means of entry to the high security building that houses all the programs

\[ P_1, P_2, \ldots \]

for the central computer. The mission will be accomplished if our agents can systematically sabotage all of these programs, ensuring that subsequently no program will operate as the enemy thinks it will. Simply to destroy the programs is not sufficient; the enemy would soon discover this and set about rewriting them. What is needed is a subtle alteration to each program, so that, unknown to the enemy, the computer will give wrong results. Swiftly and silently our men move into action...

Alas, defeat at the hands of the second Recursion theorem! Whatever systematic plan is devised to modify the programs, it will define an effectively computable function \( f \) by
\[
f(x) = \text{the code of the modification of } P_e.
\]
The second Recursion theorem springs into action, producing a number \( n \) such that \( P_n \) and its transform \( P_{c(n)} \) have the same effect (on unary inputs, at least). The operation was bound to fail.

(Sometime later, back at H.Q., our master strategists consider recruiting a chimpanzee whose mission is to alter the programs in random fashion...)

1.10. Exercises

1. Show that there is a number \( n \) such that \( \phi_{i(n)}(x) = [\sqrt{x}] \)
2. Show that there is a number \( n \) such that \( W_n = E_n = n\mathbb{N} \).
3. Show that there is a number \( c \) such that \( \phi_{c(n)}(x) = c^2 \) for all \( x \).
4. Is there a number \( n \) such that \( W_n = \{ x : \phi_{c(n)}(x) \} \)?
5. Suppose that \( \mathcal{A} \subseteq \mathcal{C} \), and let \( A = \{ x : \phi_{c(x)} \in \mathcal{A} \} \). Show that \( A \subseteq \mathcal{M} \).

Deduce theorem 1.6.

6. Give an example of a total computable function \( f \) such that (1) \( \phi_{c(x)} \) is total, then so is \( \phi_{c(n)} \), (ii) there is no fixed point \( n \) for \( f \) with \( \phi_{c(n)} \) total.

7. Prove the second Recursion theorem for \( k \)-ary computable functions: if \( f \) is a total computable function there is a number \( n \) such that \( \phi_{c(n)}(x) = \phi_k(x) \).

8. Show that theorem 1.1 may be improved to: For any total computable function \( f \), there is an increasing recursive function \( n(t) \) such that for every \( t \), \( \phi_{n(t)} = \phi_{n(t)} \).

(Hint. Examine the proof of theorem 1.1; note first that from our proof of the \( s-m-n \) theorem we have \( s(x) = x \) for all \( x \) or else show that by adding some redundant instructions to the end of \( P_{c(x)} \), an equally suitable computable function \( s(x) \) can be found, with \( s'(x) = x' \). Now observe that given any number \( k \), we can effectively find an index \( m \) for \( s(x) \) with \( m \geq k \). Then, following the proof of theorem 1.1, we have that \( n = s(m) \) is a fixed point for \( f \), and \( n = s(m) \geq n \geq k \). It is now a simple matter to construct a function \( n(t) \) as required.)

9. Prove that theorem 1.2 does not depend on the particular effective numbering of programs that is chosen.

(Hint. Let \( \delta \) be another effective numbering of programs; let \( Q_m = \) program given code number \( m \) by \( \delta \); let \( \phi_{\delta} = \) the unary function computed by \( Q_m \). We have to prove that for any total computable function \( f \), there is a number \( n \) such that \( \phi_{c(n)} = \phi_{\delta} \).

2. Discussion

The second Recursion theorem and its proof may seem a little mysterious at first. We shall see, however, that it is essentially a simple diagonal argument applied to effective enumerations of computable functions.

Suppose that \( h \) is a computable function. If \( h \) is total, then the enumeration \( E \) given by

\[ E(n) = \phi_{n(h(n))}, \phi_{n(h(n))} \ldots \]

is an effective enumeration of computable functions. If \( h \) is not total, we can still regard \( h \) as enumerating a sequence of computable functions \( E \) by adopting the convention that for any \( x \), the expression \( \phi_{n(h)} \), denotes the function given by

\[ \phi_{n(h)}(y) = \begin{cases} \phi_{n(h)}(y) & \text{if } h(x) \text{ is defined}, \\ \text{undefined} & \text{if } h(x) \text{ is undefined}. \end{cases} \]

Thus, if \( h(x) \) is undefined, \( \phi_{n(h)} \) is the function that is nowhere defined.

The following lemma shows that the sequence \( E \) thus enumerated by \( h \) is an effective enumeration even when \( h \) is not total.

2.1. Lemma

Suppose that \( h \) is a computable function. There is a total computable function \( h' \) such that \( h \) and \( h' \) enumerate the same sequence of computable functions.

Proof. The \( s-m-n \) theorem gives a total \( h' \) such that

\[ \phi_{n(h)}(y) = \phi_{n(h')(x, y)}. \]

We can now explain the idea underlying the proof of the Recursion theorem. For any \( k \), let us denote by \( E_k \) the sequence of computable...
functions effectively enumerated by $\phi_n$; then the list $E_0, E_1, E_2, \ldots$ includes all possible effective enumerations of computable functions. We can display the details of these enumerations as follows (ignore the circles):

$$
E_0: \phi_{\alpha(0)}, \phi_{\alpha(1)}, \phi_{\alpha(2)}, \ldots, \phi_{\alpha(n)}, \ldots
$$

$$
E_1: \phi_{\alpha(0)}, \phi_{\alpha(1)}, \phi_{\alpha(2)}, \ldots, \phi_{\alpha(n)}, \ldots
$$

$$
E_2: \phi_{\alpha(0)}, \phi_{\alpha(1)}, \phi_{\alpha(2)}, \ldots, \phi_{\alpha(n)}, \ldots
$$

Then the diagonal enumeration, $D$, circled on this array, is given by

$$
D: \phi_{\beta(0)}, \phi_{\beta(1)}, \phi_{\beta(2)}, \ldots
$$

Thus $D$ is an effective enumeration, given by the computable function $h(x) = \phi_\beta(x)$. Moreover, $D$ has an entry in common with each effective enumeration $E_i$; in fact, for each $k$, $D$ and $E_k$ have their $(k+1)$th entry $\phi_{\beta(k)}$ in common.

Suppose now that $f$ is a total computable function. Then we can 'operate' on $D$ to give an enumeration $D^*$ given by

$$
D^*: \phi_{f(\beta(0))}, \phi_{f(\beta(1))}, \phi_{f(\beta(2))}, \ldots
$$

Now $D^*$ is an effective enumeration of computable functions (given by $f(h(x))$) so there is a number $m$ such that $D^* = E_m$. By Lemma 2.1 we may assume that $\phi_m$ is total. As noted above, $D$ and $E_m$ have their $(m+1)$th entry in common, i.e.

$$
\phi_{\beta(m)}(x) = \phi_{f(\beta(m))}(x)
$$

Since $\phi_m$ is total, the number $\phi_m(m) = n$, say, is defined, and

$$
\phi_n = \phi_{f(m)}.
$$

The argument is simply illustrated as follows:

$$
D:
\begin{array}{c}
E_0: \phi_{\alpha(0)}, \phi_{\alpha(1)}, \phi_{\alpha(2)}, \ldots, \\
E_1: \phi_{\alpha(0)}, \phi_{\alpha(1)}, \phi_{\alpha(2)}, \ldots, \\
E_2: \phi_{\alpha(0)}, \phi_{\alpha(1)}, \phi_{\alpha(2)}, \ldots, \\
\vdots
\end{array}
$$

$$
D^* = E_m: \phi_{f(\beta(0))}, \phi_{f(\beta(1))}, \phi_{f(\beta(2))}, \ldots, \phi_{f(\beta(m))}, \phi_{\beta(m)} = \phi_{\alpha(n)}(m)
$$

So $n = \phi_m(m)$ is a fixed point.

Note: This proof can be rephrased to appear similar to standard diagonal arguments as follows. Suppose that $f$ is a total function such that $\phi_{f(n)} \neq \phi_n$ for all $n$: then using $f$ on the diagonal enumeration $D$, the enumeration $D^*$ is constructed so as to differ from $E_n$ at $k$ (fulfilling the requirements of the diagonal motto). Hence $D^*$ is not an effective enumeration, so $f$ cannot be computable.

The second Recursion theorem can thus be viewed as a generalisation of many earlier diagonal arguments. To illustrate this, we show how to use the second Recursion theorem to prove that $K$ is not recursive, one of the fundamental diagonal arguments.

2.2 Theorem

$K$ is not recursive.

Proof. Let $a, b$ be indices such that $W_a = \mathbb{Z}$ and $W_b = \mathbb{N}$. If $K$ is recursive, then the function $g$ defined by

$$
g(x) = \begin{cases} a & \text{if } x \in K, \\
 b & \text{if } x \notin K,
\end{cases}
$$

is computable. Notice that $g$ has the property that for all $x$

$$
W_{g(x)} \neq W_a,
$$

(since $x \in W_{g(x)} \iff W_{g(x)} = \mathbb{N} \iff g(x) = b \iff x \notin W_a$). This is in contradiction to the second Recursion theorem. □

Remark. We have, of course, used a sledge hammer to crack a nut. The point about this proof is that all diagonalisation is hidden inside the application of the Second Recursion theorem. We are not suggesting that the earlier proof should be replaced by this one.

The relationship between the two Recursion theorems Suppose that $\phi: \mathbb{N} \to \mathbb{N}$ is a recursive operator, and that $h$ is a total computable function such that $\phi(x) = \phi_{h(x)}$ for all $x$ (as given by the Myhill–Shepherdson theorem). If $n$ is a fixed point for $h$, then $\phi_{h(n)} = \phi_n$, i.e.

$$
\phi(n) = \phi_n.
$$

Thus the second Recursion theorem tells us (as does the first theorem) that $\phi$ has a computable fixed point; it does not tell us, however, that $\phi$ has a computable least fixed point. So, for recursive operators the first Recursion theorem gives us more information.

On the other hand, the second Recursion theorem applies to non-extensional computable functions as well; i.e. functions that do not arise from recursive operators. Thus the second theorem has a wider range of application than the first theorem, although in the area of overlap it generally gives less information. Thus, these two theorems are best regarded as complementary, although a case is made by Rogers [1967] for the view that the second theorem is the more general of the two.
3. **Myhill's theorem**

Let us now formulate and prove the generalisation of theorem 1.1 needed for Myhill's theorem. Suppose we have a total computable function \( f(x, z) \); theorem 1.1 shows that for any particular value of the parameters \( z \) there is a number \( n \) such that \( \phi_{\langle n, z \rangle} = \phi_n \). We now show that \( n \) can be obtained effectively from \( z \).

3.1. **Theorem** (The second Recursion theorem)

Suppose that \( f(x, z) \) is a total computable function. There is a total computable function \( n(z) \) such that for all \( z \)

\[
\phi_{\langle n(z), z \rangle} = \phi_{\langle n, z \rangle}.
\]

**Proof.** We simply introduce the parameter at appropriate points in the proof of theorem 1.1.

By the \( s-m-n \) theorem there is a total computable function \( s(x, z) \) such that

\[
(*) \quad \phi_{\langle s(x), z \rangle} = \phi_{\langle s(z), x \rangle}.
\]

Then, again by using the \( s-m-n \) theorem, there is a total computable function \( m(z) \) such that \( s(x, z) = \phi_{\langle m(z), x \rangle} \). Rewriting \((*)\) we have

\[
\phi_{\langle s(x), z \rangle} = \phi_{\langle s(m(z)), x \rangle}.
\]

Then, putting \( x = m(z) \) and setting \( n(z) = \phi_{\langle m(z), m(z) \rangle} \) we have

\[
\phi_{\langle n(z), z \rangle} = \phi_{\langle n, z \rangle},
\]

as required. \( \square \)

We proceed immediately with the proof of Myhill's theorem (theorem 9.3.5).

3.2. **Myhill's theorem**

Any creative set is \( m \)-complete.

**Proof.** Suppose that \( A \) is creative and \( B \) is \( e \)-e.; we must prove that

\[
B \equiv_m A.
\]

Let \( p \) be a productive function for \( \bar{A} \). Define a function \( f(x, y, z) \) by

\[
f(x, y, z) = \begin{cases} 
0 & \text{if } z = p(x) \text{ and } y \in B, \\
\text{undefined} & \text{otherwise.}
\end{cases}
\]

Then \( f \) is computable, so by the \( s-m-n \) theorem there is a total computable function \( s(x, y) \) such that

\[
\phi_{\langle s(x), y \rangle} = f(x, y, z).
\]

Then, in particular

\[
W_{\langle x, y \rangle} = \begin{cases} 
\{p(x)\} & \text{if } y \in B, \\
\emptyset & \text{otherwise.}
\end{cases}
\]

By the second Recursion theorem (theorem 3.1) there is a total computable function \( n(y) \) such that

\[
W_{\langle x, n(y) \rangle} = W_{\langle x, y \rangle}
\]

for all \( y \). Thus, for all \( y \)

\[
W_{\langle y \rangle} = \begin{cases} 
\{p(n(y))\} & \text{if } y \in B, \\
\emptyset & \text{otherwise.}
\end{cases}
\]

We claim now that

\[(**) \quad y \in B \leftrightarrow p(n(y)) \in A.\]

(a) Suppose that \( y \in B \); then \( W_{\langle y \rangle} = \{p(n(y))\} \). If \( p(n(y)) \notin A \), then \( W_{\langle y \rangle} \notin A \), so by the productive property of \( p \), \( p(n(y)) \notin W_{\langle y \rangle} \). This is a contradiction. Hence \( p(n(y)) \in A \).

(b) Suppose that \( y \notin B \); then \( W_{\langle y \rangle} = \emptyset \subseteq A \). By the productive property of \( p \), \( p(n(y)) \in A \).

The claim \((**\)\) is thus established, so \( B \equiv_m A \) since \( p(n(y)) \) is computable. \( \square \)

3.3. **Corollary**

The \( m \)-degree \( 0_m \) consists of all creative sets.

3.4. **Exercises**

1. Prove the following generalisation of theorem 3.1: For any number \( k \) there is a total computable function \( \phi_{\langle n, z \rangle} \) (where \( z = \langle z_1, \ldots, z_k \rangle \)) with the following property: if \( z \) is such that \( \phi_{\langle n, z \rangle} \) is defined for all \( x \), then

\[
\phi_{\langle n, z \rangle} = \phi_{\langle n, z \rangle}.
\]

(Hint. This can in fact be derived as a corollary to theorem 3.1.)

2. Formulate and prove the result that improves theorem 3.1 in the same way that exercise 1.10(8) improves theorem 1.1.
12

Complexity of computation

In the real world of computing, the critical question about a function $f$ is not Is $f$ computable?, but rather Is $f$ computable in practical terms? In other words, is there a program for $f$ that will compute $f$ in the time (or space) we have available? The answer depends partly on our skill in writing programs and the sophistication of our computers, but intuitively we feel that there is an additional factor which can be described as the 'intrinsic complexity' of the function $f$ itself. The theory of computational complexity, which we introduce in this chapter, has been developed in order to be able to discuss such questions and to aid the study of the more practical aspects of computability.

Using the URM approach, we can measure the time taken to compute each value of a function $f$ by a particular program, on the assumption that each step of a URM computation is performed in unit time. The time of computation thus defined is an example of a computational complexity measure that reflects the complexity of the program being used. (Later we shall mention other complexity measures.)

With a notion of complexity of computation made precise, it is possible to pursue questions such as: How intrinsically complex is a computable function $f$? and Is it possible to find a 'best' program for computing $f$?

The theory of computational complexity is a relatively new field of research; we shall present a small sample of results that have a bearing on the questions raised above. At the end of the chapter we shall provide suggestions for the reader wishing to pursue this topic further.

We begin in §1 by defining some notation; after some discussion we proceed to show that there are arbitrarily complex computable functions. Section 2 is devoted to the surprising and curious Speed-up theorem of M. Blum, which shows in particular that there are computable functions having no 'best' program. In §3 we introduce the idea of complexity classes and prove Borodin's Gap theorem; in the final section we show how we can use complexity classes to give a pleasant characterisation of the elementary functions—an important subclass of the primitive recursive functions.

1. Complexity and complexity measures

We begin by establishing some notation.

1.1. Notation

(a) For any program $P$, we write $t_P^{(n)}(x)$ for the function given by

$$t_P^{(n)}(x) = \begin{cases} \text{the number of steps taken} \\ \text{by } P \text{ to compute } f_P^{(n)}(x), & \text{if } f_P^{(n)}(x) \text{ is defined} \\ \text{undefined} & \text{otherwise} \\ = \mu(t(P|x) \downarrow \text{in } t \text{ steps}) \end{cases}$$

(b) For any index $e$ we write $t_e^{(n)}(x)$ for $t_P^{(n)}(x)$. We shall write $t_e^{(n)}$ for $t_P^{(n)}$ and $t_e$ for $t_P^{(n)}$ as is customary.

The collection of time functions $t_e^{(n)}$ constitutes an example of a computational complexity measure. Some simple but important properties of these functions are given in the following lemma.

1.2. Lemma

(a) $\text{Dom}(t_e^{(n)}) = \text{Dom}(\phi_e^{(n)})$, all $n, e$.

(b) For each $n$ the predicate $M(e, x, y)$ defined by $M(e, x, y) = t_e^{(n)}(x) = y$ is decidable.

Proof. (a) is obvious; (b) follows from corollary 5-1.3. □

Remark. The property (b) is used frequently in complexity theory; it stands in marked contrast to the fact that $\phi_e^{(n)}(x) = y$ is an undecidable predicate.

Often in complexity theory a property holds for all sufficiently large numbers $n$, though not necessarily for all $n$. Thus we make the following definition.

1.3. Definition

A predicate $M(n)$ holds for almost all $n$, or almost everywhere (a.e.) if $M(n)$ holds for all but finitely many natural numbers $n$ (or, equivalently, if there is a number $n_0$ such that $M(n)$ holds whenever $n \geq n_0$).

We can now state our first theorem, which shows that there are arbitrarily complex computable functions.
1.4. **Theorem**

Let \( b \) be a total computable function. There is a total computable function \( f \), taking only the values 0, 1, such that if \( e \) is any index for \( f \), then

\[
\mu_e(n) > b(n) \text{ a.e.}
\]

**Proof.** The reader should not be surprised to find that \( f \) is obtained by a diagonal construction. The essence of the construction is to ensure that if \( \mu_e(m) \leq b(m) \) for infinitely many values \( m \), then \( f \) differs from \( \phi_e \) at one of those values. We define \( f \) by recursion as follows.

At each stage \( n \) in the construction of \( f \) we shall either define an index \( i_n \), or decide in a finite amount of time that \( i_n \) is to be undefined. We then ensure that \( f(n) \) differs from \( \phi_{i_n}(n) \) if \( i_n \) is defined. In detail, assuming that \( f(0), \ldots, f(n-1) \) have been thus defined, we put

\[
i_n = \begin{cases} 
   \mu_{i_n} & \text{if such an } i_n \text{ exists,} \\
   \text{undefined} & \text{otherwise.}
\end{cases}
\]

\[
f(n) = \begin{cases} 
   1 & \text{if } i_n \text{ is defined and } \phi_{i_n}(n) = 0, \\
   0 & \text{otherwise.}
\end{cases}
\]

There is a finite procedure that tells us for a given \( i \) whether \( \mu_i(n) \leq b(n) \), since

\[
\mu_i(n) \leq b(n) \iff \exists y \leq b(n) \mu_i(n) = y,
\]

and the right hand side is decidable by lemma 1.2(b). Hence there is an effective procedure to decide whether \( i_n \) is defined, and if so, to find its value. Moreover, if \( i_n \) is defined, then so is \( \phi_{i_n}(n) \). Hence \( f \) is a well-defined total computable function.

Suppose now that \( f = \phi_e \); by construction \( e \neq i_n \) whenever \( i_n \) is defined. We shall show that if \( f = \phi_e \) is any index such that \( \mu_e(m) \leq b(m) \) for infinitely many \( m \), then \( i = i_n \), for some \( n \), and hence \( i \neq e \). This is sufficient to show that \( \mu_e(m) > b(m) \) for almost all \( m \).

Suppose then that \( \mu_e(m) \leq b(m) \) for infinitely many \( m \). Let \( p = 1 + \max(k: i_k \text{ is defined and } i_k < i) \); put \( p = 0 \) if there are no defined \( i_k < i \).

Choose \( n \) such that \( n \leq i, p \text{ and } \mu_e(n) \leq b(n) \). If \( i = i_k \) for some \( k < n \), there is nothing further to prove. Assuming then that \( i \neq i_k \) for all \( k < n \), we have at stage \( n \):

\( i \leq n \) and \( i \) differs from all previously defined \( i_k \) and \( \mu_i(n) \leq b(n) \).

Thus, from the definition of \( i_n \), \( i_n \) is defined and \( i_n \leq i \). But since \( n \geq p \), we must have \( i_n = i \). Hence \( i_n = i \), as required. □

We cannot in general improve this theorem to obtain the conclusion \( \mu_e(n) > b(n) \) for all \( n \); this is because for any \( f \) we can always write a program that computes \( f \) quickly for some particular value \( a \), simply by specifying the value of \( f(a) \) in a preface to the program. For example, suppose that \( f(a) = 1 \); let \( F \) be a program that computes \( f \). Then the program \( F' \) based on the flow diagram in fig. 12a also computes \( f \). Clearly we have \( \mu_{F'}(a) = a + 3 \). Thus, if \( b \) is a computable function such that \( b(x) > x + 3 \) for some \( x \), then we cannot obtain the conclusion of theorem 1.4 with \( \mu_e(n) > b(n) \) for all \( n \).

Using a similar idea we can write a program that computes \( f \) quickly for any given finite number of values; see exercise 1.8(1) below. This shows that \( \mu_e(n) > b(n) \) a.e. is the best possible conclusion in theorem 1.4.

**Other computational complexity measures.** There are many other natural ways to measure the complexity of a computation, of which the following are a few examples. For simplicity we restrict our discussion to unary computations.

---

**Fig. 12a.**

```
START

a -> R

k = r?

No

Yes

r_i := 0

r_{i+1} := r_i + 1

STOP
```

---
3. For the complexity measures given in example 1.5(3), verify lemma 1.6, expressed in the following terms. For any Turing machine \( M \), let \( f_M \) be the unary function computed by \( M \). Then show that

\( \text{(a)} \) \( \text{Dom}(\Phi_M) = \text{Dom}(f_M) \).
\( \text{(b)} \) \( \Phi_M(x) = y \) is decidable

(i) when
\[
\Phi_M(x) = \begin{cases} 
\text{the number of steps taken in computing } f_M(x) & \text{using } M, \ \text{if } f_M(x) \text{ is defined,} \\
\text{undefined} & \text{otherwise.}
\end{cases}
\]

(ii) when
\[
\Phi_M(x) = \begin{cases} 
\text{the length of tape actually used}\footnote{We say a square on the tape is used if it is scanned during the computation or lies between the outermost non-blank squares on the initial tape (including these outermost squares).} \text{in the} & \text{computation of } f_M(x) \text{ by } M, \ \text{if } f_M(x) \text{ is defined,} \\
\text{undefined} & \text{otherwise.}
\end{cases}
\]

4. Suppose that \( \Phi_\varepsilon(x) \) and \( \Psi_\varepsilon(x) \) are two abstract computational complexity measures. Show that \( \Phi_\varepsilon \) and \( \Psi_\varepsilon \) are recursively related in the following sense: there is a recursive function \( r \) such that for any \( \varepsilon \)
\[
\Psi_\varepsilon(n) = r(n, \Phi_\varepsilon(n)) \quad \text{and} \quad \Phi_\varepsilon(n) = r(n, \Psi_\varepsilon(n))
\]
for almost all \( n \) for which \( \Phi_\varepsilon(n) \) and \( \Psi_\varepsilon(n) \) are defined. \( \text{Hint.} \) Consider the function \( r \) defined by \( r(n, m) = \max(\Phi_\varepsilon(n), \Psi_\varepsilon(n)) \) if \( n \leq m \) and \( \Phi_\varepsilon(n) = m \) or \( \Psi_\varepsilon(n) = m \).

Show further that if \( \Phi_\varepsilon(n), \Psi_\varepsilon(n) \geq n \) whenever defined, there is a recursive function \( r \) such that \( \Psi_\varepsilon(n) \leq r(\Phi_\varepsilon(n)) \) and \( \Phi_\varepsilon(n) \leq r(\Psi_\varepsilon(n)) \) whenever \( \Phi_\varepsilon(n) \) and \( \Psi_\varepsilon(n) \) are defined.

2. The Speed-up theorem

Suppose that \( P \) and \( Q \) are programs for computing a total function \( f \) such that for any \( x \)
\[ 2Q(x) < P(x). \]
We would naturally say that \( Q \) is more than twice as fast as \( P \). One instance of the Speed-up theorem tells us that there is a total function \( f \) with the following property: if \( P \) is any program for \( f \), then there is another program for \( f \) that is more than twice as fast on almost all inputs. Thus, in particular, there can be no best program for computing \( f \).

The Speed-up theorem will give speed-up by any preassigned (computable) factor: the example above represents speed-up by a factor of 2, given by the computable function \( r(x) = 2x \). The proof of this theorem is probably the most difficult in this book. First we prove a pseudo-speed-up theorem, which contains most of the work. The Speed-up theorem then follows quite easily.

2.1. The pseudo-Speed-up theorem (Blum)

Let \( r \) be a total computable function. There is a total computable function \( f \) such that given any program \( P \) for \( f \), we can find \( P \) with the properties

\( \text{(a)} \) \( f \) is total and \( f(x) = f(x) \) a.e.,
\( \text{(b)} \) \( r(t(x)) < t(x) \) a.e.

(Note. This is pseudo-speed-up in that we do not necessarily have \( f(x) = f(x) \) for all \( x \), as will be the case in the Speed-up theorem.)

Proof. First we must fix a particular total computable function \( s \) given by the \( x \)-dependent theorem, such that \( f(x) = f(x) \).

We shall find a particular index \( e \) such that \( f(x) \) is total and has the following properties, where we write \( g_e \) for the function given by \( g_e(x) = f(x) \):

\( \text{(a)} \) \( g_e = f \), the function required in the statement of the theorem,
\( \text{(b)} \) for any \( u \), \( g_u(x) = g_u(x) \) a.e.,
\( \text{(c)} \) \( f = f \), then there is an index \( i \) for \( g_{i+1} \) such that \( r(t_i(x)) = t_i(x) \) a.e., in fact we can take \( i = s(e, i-1) \).

Clearly this is sufficient to prove the theorem.

For the moment think of \( e \) as arbitrary but fixed. Thinking of \( u \) as a parameter, we shall define a computable function \( g(u, x) \), which will also depend implicitly on \( e \) in an effective way. For a particular \( e \) which will be chosen later, \( g \) will be the function \( f(x) \) above. The definition of \( g \) is by recursion on \( x \), with \( u \) fixed, as follows.

For any \( x, g(u, x) \) is defined only if \( g(u, 0), \ldots, g(u, x-1) \) have all been defined, and in the process some finite sets of cancelled indices \( C_0, C_1, \ldots, C_{x-1} \) have been defined. Suppose that this is the case.

Now set
\[
C_{ux} = \begin{cases} 
\{ i : u \leq i < x, i \in \bigcup \limits_{y < x} C_y \text{ and } t_i(x) \leq r(t_{i(x-1)}(x)) \} \\
\text{if } t_{i+1}(x) \text{ is defined for } u \leq i < x, \\
\text{undefined} & \text{otherwise.}
\end{cases}
\]

(Of course, if \( x < u \) then \( C_{ux} = \emptyset \) and is defined). Note that if \( t_{i+1}(x) \) is defined, we can decide whether \( t(x) = r(t_{i(x-1)}(x)) \) (using lemma 1.2(b)), whether or not \( t_i(x) \) is defined.
Then \( g(u, x) \) is given by
\[
g(u, x) = \begin{cases} 
1 - \max \{ \phi_i(x) : i \in C_{ux} \} & \text{if } C_{ux} \text{ is defined,} \\
\text{undefined} & \text{otherwise.}
\end{cases}
\]
(If \( C_{ux} \) is defined, then for any \( i \in C_{ux} \) we must have \( \phi_i(x) \) defined, so \( g(u, x) \) is certainly defined in this case.)

By Church's thesis, \( g \), as thus defined, is a computable partial function which depends implicitly and effectively on the value of \( e \). Hence, by corollary 11.1.4 to the second Recursion theorem (slightly generalised) there is an index \( e \) such that
\[
g(u, x) = \phi_e^{(2)}(u, x).
\]
From now on let \( e \) be a fixed index such that (**) holds; then \( e \) is the index mentioned at the beginning of the proof. We must verify that it has the required properties.

First we show that (**) implies that \( g \) is total. Fix \( x \); for \( u \approx x \), \( C_{ux} = \emptyset \) so \( g(u, x) = 1 \) immediately from the definition. For \( u < x \) we show that \( g(u, x) \) is defined by reverse induction on \( u \). Suppose then that \( g(x, x), g(x - 1, x), \ldots, g(x + 2, x), g(u + 1, x) \) are all defined. Then from (**) and the definition of \( x \) we have \( \phi_{(x-1)}(x), \phi_{(x+1)}(x), \ldots, \phi_{(u+2)}(x) \) are all defined; hence so are \( t_{(u+1)}(x) \) for \( u = i < x \). This in turn means that \( C_{ux} \) is defined, hence \( g(u, x) \) is defined also. Thus \( g(u, x) \) is a total function.

Now, writing \( g_u \) for the function given by \( g_u(x) = g(u, x) \) we have
\[
g_u(x) = g(u, x)
= \phi_e^{(2)}(u, x) \quad \text{(from (**))}
= \phi_{(u+1)}(x) \quad \text{(by definition of \( x \)).}
\]
We must verify the properties (a)--(c) above.

(a) If we put \( f = g_u \) then \( f \) is certainly total, as required by the theorem.

(b) Fix a number \( u \); we must show that \( g(0, x) \) and \( g(u, x) \) differ for only finitely many \( x \). It is clear from the construction of the sets \( C_{ux} \) that for any \( x \)
\[
C_{ux} = C_{ux} \cap \{ u, u + 1, \ldots, x - 1 \}.
\]
Since the sets \( C_{ux} \) are all disjoint (by construction) we can find the number \( v = \max \{ x : C_{ux} \text{ contains an index } i < u \} \). Then for \( x > v \) we have \( C_{ux} \subseteq \{ u, u + 1, \ldots, x - 1 \} \), and hence \( C_{ux} = C_{ux} \). This means that \( g(0, x) = g(u, x) \) for \( x > v \). Thus \( g_0(x) = g_u(x) \) a.e.

(c) Suppose that \( i \) is an index for \( f \); taking \( j = s(e, i + 1) \) we have that \( \phi_i = \phi_{(i+1)} = g_{i+1} \) (from above), so \( j \) is an index for \( g_{i+1} \). We can prove that
\[
r(t_i(x)) = r(t_{(i+1)}(x)) < t_i(x) \quad \text{for all } x > i.
\]
If this were not the case, then \( i \) would have been cancelled in the definition of \( g(0, x) \) for some \( x > i \); i.e. there would have been \( x > i \) with \( i \in C_{ux} \). But then, by construction of \( g \), we would have \( g(0, x) = \phi_i(x) \), a contradiction. This completes the proof.

Note that the pseudo-Speed-up theorem is effective: given a program \( P \) for \( f \) we can effectively find another program that computes \( f \) almost everywhere, and is almost everywhere faster than \( P \).

We now show how to modify the above proof to obtain:

2.2. The Speed-up theorem (Blum)

Let \( f \) be any total computable function. There is a total computable function \( \tilde{f} \) such that, given any program \( P \) for \( f \), there is another program \( P_{\tilde{f}} \) for \( \tilde{f} \) such that \( \tilde{f}(x) < t_i(x) \) a.e.

Proof. We may assume without any loss of generality that \( r \) is an increasing function (or else replace \( r \) by a larger increasing computable function). First, by a slight modification of the proof of theorem 2.1 we obtain a total computable function \( \tilde{f} \) such that given any program \( P \) for \( f \), there is a program \( P_{\tilde{f}} \) such that

(a) \( \tilde{f} \) is total and \( \tilde{f}_j(y) = f(x) \) a.e.,

(b) \( r(t_i(x) + y) < t_i(y) \) a.e.

To do this, simply rewrite the definition of \( C_{ux} \), replacing \( \ldots \) and \( t_i(x) = r(t_{(i+1)}(x)) \) by \( \ldots \) and \( t_i(x) = r(t_{(i+1)}(x + x)) \). We shall show that the function \( \tilde{f} \) so obtained is the function required by the theorem.

Suppose that \( f = \phi_i \) and \( f \) is chosen with the properties (a), (b) above. Our aim now is to modify \( P_f \) to produce a program \( P_{\tilde{f}} \) that computes \( \tilde{f} \) for all \( x \). Suppose that \( \phi_i(x) = f(x) \) for all \( x > v \). Let \( f(m) = b_m \) for \( m \leq v \). We modify \( P_f \) by writing some extra instructions at the beginning designed to give these values for \( m \leq v \). Specifically, let \( P_{\tilde{f}} \) be the program that embodies the flow diagram given in fig. 12c. Clearly \( P_{\tilde{f}} \) computes \( f \); moreover, there is a number \( c \) such that the extra instructions add at most \( c \) steps to any computation; i.e. for all \( x \)
\[
t_{\tilde{f}}(x) = (t_i(x) + c).
\]
1.5. **Examples**

1. \( \Phi_e(x) = \begin{cases} \text{number of jumps made in executing } P_e(x), & \text{if } P_e(x) \downarrow, \\ \text{undefined otherwise.} & \end{cases} \)

This measure is closely associated with the number of loops performed when executing \( P_e(x) \), which is in turn related to the time of computation \( t_e(x) \).

2. \( \Phi_e(x) = \begin{cases} \text{the maximum number held in any of the registers at any time during the computation } P_e(x), & \text{if } P_e(x) \downarrow, \\ \text{undefined otherwise.} & \end{cases} \)

This measure obviously relates to the amount of storage space needed to carry out the computation \( P_e(x) \) on a real computer.

3. With the Turing machine approach, two natural complexity measures are (i) the number of steps needed to perform a Turing computation and (ii) the amount of tape used to perform a computation.

In general, an abstract computational complexity measure (for unary computations) is defined to be any collection of functions \( \Phi_e \), having the abstract properties that were given by lemma 1.2 for \( t_e \).

1.6. **Definition**

A computational complexity measure is a collection of functions \( \Phi_e \) with the following properties:

(a) \( \text{Dom}(\Phi_e) = \text{Dom}(\Phi_e) \), for all \( e \);

(b) The predicate `\( \Phi_e(x) = y \)` is decidable.

1.7. **Lemma**

The functions given in examples 1.5 above are computational complexity measures.

**Proof.** We give sketch proofs for the examples 1.5(1) and 1.5(2), leaving 1.5(3) as an exercise (1.8(3) below). In each case it is only part (b) of definition 1.6 that requires any thought:

1. To decide `\( \Phi_e(x) = y \)`, where \( \Phi_e(x) \) = number of jumps made during \( P_e(x) \). Suppose that \( P_e \) has \( s \) instructions, then at most \( s \)

Note that in proving theorem 1.4 we used only the properties of \( t_e \) given by lemma 1.2. Thus theorem 1.4 holds for any computational complexity measure. There are many other results in complexity theory which do not depend on any particular measure of complexity. Such results are said to be machine independent. The Speed-up theorem of the next section and the Gap theorem of § 3 are further examples of such results.

1.8. **Exercises**

1. Let \( f \) be a total computable function that takes only the values 0, 1. Show that for any \( m \) there is a program \( P_f \) for \( f \) such that

\[ t_e(x) \leq 2x + 3 \]

for all \( x \leq m \). Deduce that if \( b \) is a computable function such that \( b(x) > 2x + 3 \), then the restriction to almost all \( n \) in theorem 1.4 cannot be improved.

2. Let \( \Phi_e \) be the complexity measure given in example 1.5(2). Show that whenever \( \Phi_e(x) \) is defined, then \( \Phi_e(x) \geq \max(x, \Phi_e(x)) \).

Let \( f \) be any total computable function, and let \( X \) be a finite subset of \( \text{Dom}(f) \). Prove that there is a program \( P_f \) for \( f \) that is the best possible on \( X \) (for this measure); i.e. \( \Phi_e(x) = \max(x, \Phi_e(x)) \) for \( x \in X \).
2. It can be shown that the Speed-up theorem is not in general effective.

The Speed-up theorem pinpoints a problem when we try to define the complexity of a computable function \( f \) (rather than the complexity of any particular algorithm for \( f \)). We cannot define this as the complexity of the best, or fastest, algorithm for \( f \) simply because \( f \) may not have a best program.

We conclude this section with an amusing consequence of the Speed-up theorem. Suppose that we have a URM that performs 1 step per second, and we replace this with a new super-improved machine that is 100 times as fast. Then a computation \( P_i(x) \) that took \( t_i(x) \) seconds to perform on the old machine will be performed in \( t_i(x)/100 \) seconds on the new model. Consider now the function \( f \) given by the Speed-up theorem with speed-up factor of 100. Suppose that \( f \) is being computed by \( P_i \) on the new fast machine. By the Speed-up theorem there is a program \( P_j \) for \( f \) such that \( 100t_j(x) < t_i(x) \) a.e.; i.e. \( t_j(x) < t_i(x)/100 \). Thus for almost all \( x \), the old machine using \( P_i \) computes \( f \) faster than the new machine using \( P_j \).

We conclude that for some functions at least the new machine is no superior to the old one (on most inputs)!

2.3. Exercises

1. Show that in general the limitation of the inequality \( r(t_i(x)) < t_i(x) \) in the Speed-up theorem to almost all \( x \) cannot be improved.

2. Why should we regard the conclusion of the discussion in the preceding paragraph (about new and old URMs) as of theoretical rather than practical significance?

3. Complexity classes

Suppose that \( b \) is any total computable function. From the point of view of complexity, a natural class of functions comprises those functions having a program whose running time is bounded by \( b \). Thus we define

3.1. Definition

Let \( b \) be a total computable function. The complexity class of \( b \), \( \mathbb{C}_b \), is defined by

\[
\mathbb{C}_b = \{ f : f \text{ is total and } t_f(x) \leq b(x) \text{ a.e.} \}
\]

Thus we have

\[
\begin{align*}
 r(t_i(x)) & \leq r(t_i(x) + c) \quad \text{(since } r \text{ is increasing)} \\
 & \leq r(t_i(x)) \text{ for } x \geq c \\
 & < t_i(x) \text{ a.e.}
\end{align*}
\]

Hence, taking \( k = f^* \) the theorem is proved. 

Remarks

1. The above proofs of the pseudo-Speed-up and Speed-up theorems are adapted from Young [1973]. Both results hold for arbitrary complexity measures; in the case of theorem 2.1 it is clear that our proof uses only the abstract properties of the time measure \( t_i(x) \); in the proof of theorem 2.2, however, we have used some special details of the URM time measure, in estimating the relationship between \( t_i \) and \( t_j \). In Young's paper the above proof is generalised so as to work for any complexity measure.
Remark. The class $\mathcal{C}_b$ as thus defined, is the complexity class of $b$ relative to the time measure $t_e(x)$; for any measure $\Phi_e(x)$, we could define the complexity class $\mathcal{C}_b^e$ in the obvious way.

If $b'$ is another total computable function, with $b'(x) \geq b(x)$ for all $x$, of course $\mathcal{C}_b \subseteq \mathcal{C}_{b'}$; if $b'(x) > b(x)$ for all $x$, we would naturally expect that $\mathcal{C}_b$ contains some new functions not in $\mathcal{C}_b$, especially if $b'(x)$ is much larger than $b(x)$. The next theorem shows that this intuition is false: we can find $b, b'$ with $b'$ greater than $b$ by any preassigned computable factor, such that $\mathcal{C}_b = \mathcal{C}_{b'}$; in fact, the theorem shows that $b, b'$ can be chosen so that there is no running time $t_e(x)$ that lies between $b(x)$ and $b'(x)$ for more than finitely many $x$. Thus the theorem is called the Gap theorem.

3.1. The Gap theorem (Borodin)

Let $r$ be a total computable function such that $r(x) \geq x$. Then there is a total computable function $b$ such that

(a) for any $e$ and $x > e$, if $t_e(x)$ is defined and $t_e(x) \geq b(x)$, then $t_e(x) > r(b(x))$; hence

(b) $\mathcal{C}_b = \mathcal{C}_{b'}$.

Proof. We define $b(x)$ informally as follows. Define a sequence of numbers $k_0 < k_1 < \ldots < k_x$ by

$k_0 = 0,$

$k_{i+1} = r(k_i) + 1$ ($i < x$).

Consider the disjoint intervals $[k_i, r(k_i)]$ for $0 \leq i \leq x$. There are $x + 1$ such intervals, so there is at least one that does not contain any of the numbers $t_e(x)$ for $e < x$, since there are at most $x$ such numbers that are defined. Choose $t_e = t_e(x)$ for the least $i$ such that

$t_e(x) \in [k_i, r(k_i)]$ for all $e < x$.

and set $b(x) = k_i$.

Now, given that $t_e$ as defined above exists on theoretical grounds, there is an effective procedure which will find it; we simply make repeated use of lemma 1.2(b) to check $t_e(x) \in [k_i, r(k_i)]$ for various $e$ and $t$. We conclude that $b$ is a computable function, by Church's thesis.

For the conclusion of the theorem, (a), suppose that $x > e$ and $t_e(x) \geq b(x)$; by construction of $b(x)$, we have $t_e(x) \in [b(x), r(b(x))]$. Hence $t_e(x) > r(b(x))$.

4. The elementary functions

For part (b), we obviously have $\mathcal{C}_b \subseteq \mathcal{C}_{b'}$; now note that if $f \in \mathcal{C}_{b'} \cap \mathcal{C}_b$, then $f$ has a program $P$, with

$t_e(x) \leq r(b(x))$ a.e.

but

$t_e(x) > b(x)$ infinitely often (otherwise $f \in \mathcal{C}_b$).

This clearly contradicts (a). Hence $\mathcal{C}_b = \mathcal{C}_{b'}$. $\Box$

Note. This proof is based on that given by Young [1973]. It is easy to see that the function $b$ in the theorem can be made larger than any preassigned computable function $c$, simply by setting $k_0 = c(x)$ instead of $k_0 = 0$ in the proof. It is also clear from the proof that the Gap theorem is machine independent.

4.1. Definition

(a) The class $\mathcal{E}$ of elementary functions is the smallest class such that

(i) the functions $x + 1$, $U^x(i \leq i \leq n)$, $x - y$, $x - y$, $xy$ are all in $\mathcal{E}$;

(ii) $\mathcal{E}$ is closed under substitution.

(iii) $\mathcal{E}$ is closed under the operations of forming bounded sums and bounded products (i.e. if $f(x, z)$ is in $\mathcal{E}$ then the functions $\sum_{z \leq y} f(x, z)$ and $\prod_{z \leq y} f(x, z)$ are defined in chapter 2 §4).

(b) A predicate $M(x)$ is elementary if its characteristic function $c_M$ is elementary.

Roughly speaking, $\mathcal{E}$ is the class of functions that can be obtained by iteration of the operations of ordinary arithmetic. It is clear that elementary functions are computable; in fact they are all primitive recursive, by the results of chapter 2 §4. The next lemma helps to compile some examples of elementary functions and predicates.
4.2. Lemma
(a) $\mathcal{E}$ is closed under bounded minimisation.
(b) Elementary predicates are closed under 'not', 'and', 'or', and the bounded quantifiers $\forall z < y$ and $\exists z < y$.

Proof.
(a) Suppose that $f(x, z)$ is elementary; recall from the proof of theorem 2.4.12 that
$$\mu z < y (f(x, z) = 0) = \sum_{x \leq y} \prod_{x \leq u} sg(f(x, u)).$$
To see that this is elementary, just notice that $sg$ is elementary, since $sg(x) = x - (x - 1)$, and $1 = (x + 1) - x$.
(b) We leave the proof as an easy exercise. $\square$

The next theorem gives an indication of the fact that $\mathcal{E}$ is quite extensive.

4.3. Theorem
The functions $m$ (for $m \in \mathbb{N}$), and all of the functions listed in theorems 2-4.5 and 4.15 are elementary.

Proof. We shall sketch proofs for a few functions where the proof is non-trivial or differs significantly from that given in chapter 2. The terminology of chapter 2 is used throughout.
(i) $x!$. \[ x! = \prod_{x \leq y} x! \bigcup (x, i). \]
(ii) $\text{qt}$. \[ \text{qt}(x, y) = \mu z \leq y (x = 0 \text{ or } x + 1 > y) \]
\[ = \mu z \leq y (x \text{sg}(x + 1) - y) = 0. \]
(iii) $\text{rm}$. \[ \text{rm}(x, y) = y - x \text{qt}(x, y). \]
(iv) $p_n$. Assuming that the function $\text{Pr}(x)$ (the characteristic function of 'is prime') has been proved elementary, we have
$$p_n = \mu y \leq 2^n (x = 0 \text{ or } y \text{ is the } n\text{th prime})$$
$$= \mu y \leq 2^n \left(x = \sum_{x \leq y} \text{Pr}(z)\right)$$
$$= \mu y \leq 2^n \left(|x - \sum_{x \leq y} \text{Pr}(z)| = 0\right).$$
(The bound $p_n \leq 2^n$ is easily proved by induction, using the fact that $p_{n+1} \leq p \cdot \prod_{x \leq n} p$.)
We leave the proofs for the other functions as an exercise for the reader. $\square$

We now show that $\mathcal{E}$ is even closed under definitions by primitive recursion, provided that we know in advance some elementary bound on the function being defined by the recursion equations.

4.4. Theorem
Let $f(x)$ and $g(x, y, z)$ be elementary and let $h$ be the function defined from $f, g$ by
$$h(x, 0) = f(x),$$
$$h(x, y+1) = g(x, y, h(x, y)).$$
Suppose that there is an elementary function $b(x, y)$ such that $h(x, y) \leq b(x, y)$ for all $x, y$. Then $h$ is elementary.

Proof. Fix $x, y$; then the calculation of $h(x, y)$ in the usual way requires the calculation of the sequence of numbers $h(x, 0), h(x, 1), \ldots, h(x, y).$ These can be coded by the single number $s$ where:
$$s = 2^{\mu (x) 2^{\mu (x+1)} \cdots 2^{\mu (x+y)}}$$
$$= \prod_{z \leq x} p_z^{b(z)}$$
$$= \prod_{z \leq x} p_z^{b(z)} - c(x, y), \text{ say},$$
where $c(x, y)$ is an elementary function. The key facts about $s$ are
(i) $s = h(x, 0) = f(x)$,
(ii) for $z \leq y$, $s_{z+1} = h(x, z+1) = g(x, z, (s_z))$ and
(iii) $h(x, y) = (s_y)_{y+1}$. Thus we have
$$h(x, y) = [\mu z \leq c(x, y) (s_z = f(x)) \text{ and}$$
\[ \forall z < y (s_{z+1} = g(x, z, (s_z)))], \text{ so,}$$
This expression for $h$ shows that $h$ is elementary, by the results proved above. $\square$

The principle of definition described in this theorem is called limited (primitive) recursion. We shall see later that this is a weaker principle than primitive recursion. The above result is concisely expressed by saying that $\mathcal{E}$ is closed under limited recursion.

4.5. Corollary
The same function $\sigma_m$, hence the functions $e_n$ and $f_m$, defined in the proof of theorem 5-1.2 (computability of the universal functions) are elementary. Hence also the predicate $T$, of Kleene's normal form (theorem 5-1.4) is elementary.
Proof. We refer to the formal proof of theorem 5.1.2 as given in chapter 5 and completed in the appendix to that chapter. It is mostly routine to establish, by using the above results, that the functions used to build $\sigma_n$ are all elementary. For the actual definition of $\sigma_n$ by primitive recursion, note that we can obtain an elementary bound on $\sigma_n$ as follows.

It is easy to see that for any $t$

$$c_e(e, x, t) \leq \prod_{i \geq 1, i \in P(x)} p_i^{\max_{i+1}}$$

and

$$f_i(e, x, t) \leq \ln(e).$$

These two bounds are elementary functions of $e, x, t$ once we have shown that $p_1(P(x))$ and $\ln(e)$ are elementary functions. Putting these bounds together we then have an elementary bound for $\sigma_n$, and theorem 4.4 may be applied. The remainder of the proof that $\sigma_n$ is elementary consists of showing that $p_1(P(x))$, $\ln(e)$ and all the other functions defined in the appendix to chapter 5 are elementary. This is left as an exercise for the reader. (The only general principle needed but not explicitly mentioned already is that elementary functions are closed under definition by cases; see exercise 4.12(4b) below.)

The elementary nature of $c_e, f_i$ and $T_n$ follows immediately since these are all defined explicitly by substitution from $\sigma_n$ and other elementary functions. $\Box$

The following corollary is often expressed by saying that functions computable in elementary time are elementary.

4.6. Corollary

(a) Suppose that $b(x)$ is elementary and $\phi_e^{(n)}$ is a total function such that $\mu_i b(x) = b(x)$ a.e. Then $\phi_e^{(n)}$ is elementary.

(b) If $b(x)$ is elementary, then $\mathbb{E} \subseteq \mathbb{E}$.

Proof. (b) is obviously a restatement of (a) for unary functions. To prove (a), suppose that $\mu_i b(x) = b(x)$ a.e. Then the function

$$k(x) = \mu_i b(x); j_n(e, x, t) = 0$$

is elementary, and we have

$$\phi_e^{(n)}(x) = (c_e(e, x, k(x)))_1$$

a.e.

\footnote{Here we are extending the use of a.e. to $n$-ary predicates $M(x)$ in the obvious way: $M(x)$ holds a.e. if it holds for all but finitely many $n$-tuples $x$.}

By the results we have proved, the right hand side is an elementary function. To conclude that $\phi_e^{(n)}$ is elementary, we observe that a function that is almost everywhere the same as an elementary function is elementary (see exercise 4.12(4b) below). $\Box$

At this stage the reader might well be wondering whether the elementary functions coincide with the primitive recursive functions. All particular examples of primitive recursive functions from earlier chapters have been shown to be elementary. The only detectable difference between these classes is that for $\mathbb{E}$ we have only been able to prove closure under limited recursion. Could it be that this is only an apparent distinction? The answer, as we shall see below, is no. Limited recursion is a definition principle that is really weaker than primitive recursion. We will find a function that is primitive recursive but not elementary as a consequence of the next theorem to be proved below.

Nevertheless, $\mathbb{E}$ is an extremely large class of functions, and contains most of the functions used in practical mathematics. The class $\mathbb{E}$ is a natural first suggestion for the class of total effectively computable functions, based as it is on the ordinary operations of arithmetic. Indeed, it has been argued (for example, by Brainerd & Landweber [1974]) that $\mathbb{E}$ contains all practically computable functions. They argue that if $f(x)$ is practically computable, then there must be some number $k$ such that $f(x)$ can be computed in at most

$$2^{2^{k^{(x)}}}$$

steps for almost all $x$. After all, for practical purposes, this number of steps quickly becomes very large in comparison with $x$, even for small values of $k$. Now, since the function

$$2^{2^{k^{(x)}}}$$

is elementary (for fixed $k$), this means that $f$ is elementary, by corollary 4.6.

Our goal in the remainder of this section is to show that the elementary functions can be characterized as \textit{precisely} those functions that are computable in time

$$2^{2^{k^{(x)}}}$$
for some \( k \). As a first step towards that goal, we have the following, which incidentally will give a non-elementary primitive recursive function.

4.7. **Theorem**

If \( f(x) \) is elementary, there is a number \( k \) such that for all \( x \),

\[
f(x) \leq 2^{2^k x}.\]

**Proof.** Let us write \( b_k(x) \) for

\[
2^{2^k x};
\]

then, explicitly, we have \( b_0(x) = z, b_1(x) = 2^z, \) and \( b_{k+1}(x) = 2^{b_k(x)} \) in general. (Thus, by \( 2^2 \) is meant \( 2^{2^2} \), not \( (2^2)^2 \), etc.) Note that \( b_{k+1}(x) = b_k(b_k(x)) \). We shall use implicitly below the fact that \( b_k \) is increasing and that \( z^2 \leq 2^z \) for all \( z \).

To establish the theorem, we consider each of the clauses whereby a function \( f \) can get into \( \mathcal{E} \). Referring to definition 4.1:

(i) \( x + 1 \leq 2^x \);

\[
U_i^x(x) \leq \max(x);
\]

\[
x + y \leq \max(x, y);
\]

\[
x + y = 2 \max(x, y) \leq 2^{\max(x,y)};
\]

\[
xy \leq (\max(x, y))^2 \leq 2^{2 \max(x,y)};
\]

(ii) Suppose that \( h(x) = f(g_1(x), \ldots, g_m(x)) \), and \( k_1, \ldots, k_m, l \)

are such that \( g_i(x) \leq b_{k_i}(\max(x)) \) (\( 1 \leq i \leq m \)), and \( f(y) \leq b_l(\max(y)) \). Let \( k = \max(k_1, \ldots, k_m) \). Then we have

\[
h(x) \leq b_l(\max(g_1(x), \ldots, g_m(x)))
\]

\[
\leq b_l(b_k(\max(x)) = b_{k+1}(\max(x));
\]

(iii) Suppose that \( g(x, y) = \sum_{y \leq x} f(x, z) \), and that \( f(x, z) \leq b_k(\max(x, z)) \). Then we have

\[
g(x, y) = \sum_{x \leq y} b_k(\max(x, z))
\]

\[
\leq y b_k(\max(x, y))
\]

\[
\leq b_k(\max(x, y))^2
\]

\[
\leq 2^{2^{\max(x,y)}} = b_{k+2}(\max(x, y)).
\]

The case when \( g \) is a bounded product is similar, and is left as an exercise (4.12(6) below). □

4.8. **Corollary**

The function

\[
f(x) = 2^{2^k x}
\]

is primitive recursive but not elementary.

**Proof.** To see that \( f \) is primitive recursive, notice that \( f(x) = g(x, x) \), where \( g \) is defined by

\[
g(x, 0) = x,
\]

\[
g(x, y + 1) = 2^{g(x, y)};
\]

(so \( g \) is primitive recursive).

To see that \( f \) is not elementary, notice that for every \( k \)

\[
f(k + 1) > b_{k+1}(k + 1),
\]

so there is no \( k \) such that \( f(x) \leq b_k(x) \) for all \( x \). (Note that \( f \) is obtained by diagonalising out of \( \mathcal{E} \).) □

The penultimate step towards our goal is to show that elementary functions can be computed in elementary time.

4.9. **Theorem**

If \( f(x) \) is elementary, there is a program \( P \) for \( f \) such that \( t^P(x) \) is elementary.

**Proof.** We shall construct the ways in which a function gets into \( \mathcal{E} \). It is helpful to prove first the following general lemma.

4.10. **Lemma**

Let \( x = (x_1, \ldots, x_r) \). Suppose that \( h(x, y) \) is elementary, and has a definition by recursion from functions \( f(x) \) and \( g(x, y, z) \) which can be computed in elementary time. Then \( h \) can be computed in elementary time.

**Proof.** Take programs \( F, G \) for \( f, g \) in standard form, such that \( t_F \) and \( t_G \) are elementary. (For notational convenience we omit here and elsewhere the superscripts from \( t^P \) for any program \( P \) whenever the meaning is clear.) We shall take the program \( H \) for \( h \) as given in the proof of theorem 2-4.4, and show that \( t_H \) is elementary. We simply calculate \( t_H(x, y) \) by reference to the flow diagram in fig. 2c and the explicit program \( H \) that is its translation. We reproduce this flow diagram in fig. 12c, indicating alongside each component the number of steps it contributes when executed by the program \( H \). It is now a simple matter
to calculate that
\[ f_H(x, y) = n + 1 + (p(F) + t_F(x) + 1) + (y + 1) \]
\[ + \sum_{k=0}^{y} (p(G) + t_G(x, k, h(x, k)) + 3) + 1, \]
which is clearly an elementary function, since \( t_F, t_G \) and \( h \) are all elementary. □

**Proof of theorem 4.9**

Let us consider each of the clauses in the definition of \( \mathcal{E} \):

(i) The functions \( x + 1 \) and \( U^i(x) \) can each be computed by single step programs. For \( x + y, x + y, xy \) we use lemma 4.10. Consider \( x + y \), for example: this is defined by recursion from the functions \( f(x) = x \) and \( g(x, y, z) = z + 1 \), both of which are computable in elementary time.

(ii) Substitution. Suppose that \( h(x) = f(g_1(x), \ldots, g_n(x)) \), and each of \( f, g_1, \ldots, g_n \) is computable in elementary time by programs \( F, G_1, \ldots, G_n \) in standard form. Let \( H \) be the program for \( h \) given in the proof of theorem 2-3.1. Calculating directly from that program we have
\[ t_H(x) = n + \sum_{i=1}^{m} (p(G_i) + t_{G_i}(x) + 1) + p(F) \]
\[ + t_F(g_1(x), \ldots, g_n(x)) + 1, \]
which is an elementary function, by substitution.

(iii) Bounded sums and products. The result is established by using lemma 4.10. Suppose that \( g(x, y) = \sum_{i \leq y} f(i, x) \), and \( f \) is computable in elementary time. Then \( g \) is obtained by recursion from the functions \( 0 \) and \( x + f(x, y) \) both of which are computable in elementary time (from (i) and (ii) above). Hence, by lemma 4.10, \( g \) is computable in elementary time.

The proof for bounded products is similar, and is left as an exercise (4.12(8) below). □

We have now done all of the hard work! To express the characterisation of \( \mathcal{E} \) towards which we have been working, it is helpful to extend complexity classes to include \( n \)-ary functions for all \( n \). Suppose, then, that \( b(x) \) is a total function; let us write
\[ \mathcal{C}^*_{f} = \{ f : f \text{ is total and } f = \phi^{(n+1)} \text{ for some } e \text{ with } t^{(n+1)}_e(x) \leq b(\max(x)) \text{ a.e.} \} \]

Clearly \( \mathcal{C}_{b} = \mathcal{C}^*_{f} \cap \text{Unary functions.} \)

Now our final theorem is

**4.11 Theorem**

A total function \( f(x) \) is elementary if it is computable in time \( \leq b_x(\max(x)) \), for some \( k \), i.e.
\[ \mathcal{E} = \bigcup_{k=0}^{\infty} \mathcal{C}^*_{b_k} \]

**Proof.** Since for each \( k, b_k(\max(x)) \) is an elementary function, we have \( \mathcal{C}^*_{b_k} \subseteq \mathcal{E} \) by corollary 4.6; hence
\[ \bigcup_{k=0}^{\infty} \mathcal{C}^*_{b_k} \subseteq \mathcal{E}. \]
For the converse inclusion, let \( f(x) \) be an elementary function. By theorem 4.9 there is a program \( F \) for \( f \) such that \( t_F \) is elementary; now by theorem 4.7 find a number \( k \) such that \( t_F(x) \leq b_k(\max(x)) \). Then \( f \in \mathcal{E}_k \), so our proof is complete. \( \square \)

4.12. Exercises
1. Show that it was not strictly necessary to include the functions \( x - y \) and \( xy \) in the definition of \( \mathcal{E} \). \( \text{Hint.} \) First obtain \( xy \) as a bounded sum; then obtain \( x - y \) from suitable products, using \( - \).
2. Prove lemma 4.2(b).
3. Complete the proof of theorem 4.3.
4. (a) Show that \( \mathcal{E} \) is closed under definition by cases, when the functions and predicates in the definition are all elementary.
   (b) Show that if \( f(x) \) is elementary and \( g(x) = f(x) \) a.e., then \( g(x) \) is elementary.
5. Check all the details in the proof of corollary 4.5.
6. Complete the proof of theorem 4.7 by showing that if \( g(x, y) = \prod_{z \leq x} f(x, z) \) and \( f(x, z) \leq b_k(\max(x, z)) \), then \( g(x, y) \leq b_{k+3}(\max(x, y)) \).
7. Give an example of a unary primitive recursive function that is not elementary, different from that of corollary 4.8.
8. Prove that if \( f \) is computable in elementary time and \( g(x, y) = \prod_{z \leq x} f(x, z) \), then \( g \) is computable in elementary time.
9. Suppose that \( \Phi_e \) is a complexity measure for unary functions that is related to \( t_e \) by an elementary function \( t \). I.e. for any \( e \), and almost all \( x \) for which \( t_e(x) \) is defined,
   \[ \Phi_e(x) = r(x, t_e(x)) \text{ and } t_e(x) \leq r(x, \Phi_e(x)) \].
   For any total function \( b(x) \), let \( \mathcal{E}_b^\Phi \) be the complexity class of \( b \) relative to \( \Phi \), i.e.
   \[ \mathcal{E}_b^\Phi = \{ \Phi_e : \Phi_e \text{ is total and } \Phi_e(x) \leq b(x) \text{ a.e.} \} \].
   Prove that \( \bigcup_{k=0}^{\infty} \mathcal{E}_k^\Phi = \mathcal{E}_1 \), the unary elementary functions.

Further reading  For a fuller treatment of the machine independent theory of complexity, the reader should consult the basic paper of Blum [1967], or the readable overview of the theory by Hartmanis & Hopcroft [1971]. The paper of Young [1973], which we have already cited in earlier sections, simplifies some of the proofs of basic theorems. The book of Brainerd & Landweber [1974] has a good chapter on complexity, and also gives the characterisation of various subrecursive classes of functions (including \( \mathcal{E} \)) in terms of time of computation. Similar characterisations are also discussed in the early (in the history of complexity theory) papers of Ritchie [1962] and Cobham [1965], using the Turing machine tape measure of complexity.
Further study

Our basic study of computability has been designed so that it could serve as a stepping stone to more advanced or more detailed study in any of several directions. In this brief postlude, we shall mention some of the areas in which further study could be pursued, and we offer some suggestions for further reading. The divisions below are not hard and fast, and there are many interrelations between the various areas we mention.

Computability. Further study of the theoretical notion of computability (the starting point of this book) could be pursued in two directions: (a) more detailed examination of other equivalent approaches to computability (which we surveyed in chapter 3); (b) examination of more restricted notions of effective computability, involving, for instance, finite automata and similar devices.

Some references (several historical) for (a) were given in chapter 3. For both (a) and (b) we suggest the books of Minsky [1967] (a very comprehensive treatment), Arbib [1969], or Engeler [1973].

Recursion theory. We use this traditional title under which to mention more advanced ideas arising out of the notion of computability on \( \mathbb{N} \), such as we began to pursue in chapters 7, 9 to 11. Specific areas include:

Hierarchies: there are various ways to extend the sequence beginning 'recursive, r.e., . . . ' to obtain a hierarchy of kinds of set, each kind of set having more difficult decision problem than the preceding one. Among the important hierarchies that have been studied are the arithmetical hierarchy, the hyperarithmetical hierarchy, and the analytical hierarchy.

Reductions and degrees: between \( \leq_\text{m} \) and \( \leq_\text{t} \) there is a spectrum of reducibilities that could be investigated. For the student wishing to delve further into Turing reducibility, the next step would be to master a proof of the Friedberg-Muchnik solution to Post's problem, before proceeding to further results and proofs in this area, some of which we mentioned in chapter 9.

Recursion in higher types: we considered briefly in chapter 10 the question of computable functions of functions. This study can be extended to computability of functions of functions of functions, etc. Hierarchies occur naturally here also.

The book of Rogers [1967] is the best single reference for each of these areas, in that it is a more advanced and comprehensive textbook which continues these topics where we have concluded our introduction. More specific sources of information about degrees are Sacks [1963], Soare [1971] and Simpson [1977].

Under this heading we should also mention

Generalized recursion theory: This is a relatively new field of study, in which ideas arising in computability on \( \mathbb{N} \) are transferred to other structures that are not merely coded-up disguises of \( \mathbb{N} \). This development has been particularly successful on certain sets called admissible ordinals. An introductory article having a large annotated bibliography is provided by Shore [1977] in the Handbook of Mathematical Logic (Barwise [1977]).

Decidability and undecidability. A good survey of unsolvable problems in general is provided in the article by Davis [1977] in the Handbook of Mathematical Logic.

For an introduction to mathematical logic, and decidability and undecidability in this area, there are numerous basic texts, such as Mendelson [1964] or Robbin [1969]. These books also give a complete treatment of Gödel's theorem and related results. For more advanced study in this area, there are texts such as Bell & Machover [1977], and Boolos & Jeffrey [1974]. The article by Rabin [1977] surveys methods and results on the decidability of mathematical theories.

Computer science. The study of topics included under the heading Computability above, especially finite automata, is of course relevant to computer science—which could be called 'the realm of practical computability. Within this realm there are two areas we have touched on, albeit briefly:
Programs and programming: further study here could include topics such as the generation of programming languages and the structure of programs; and the semantics of programming languages (which we touched upon in chapter 10). Texts which cover these matters include Aribib [1969], Bird [1976], Brainerd & Landweber [1974], Engeler [1973] and Manna [1974].

Complexity theory: at the end of chapter 12 we offered some suggestions for further reading in this area. There is considerable interest in identifying functions $f(x)$ that can be computed in an amount of time bounded by some polynomial in $x$. A major unsolved problem here is the so-called $P = NP$ problem: machines are considered in which there is a certain amount of freedom in choosing the next step in a computation (such machines are called non-deterministic). By making good guesses (or choices) one can often obtain a quicker computation than by systematically working through all possible cases in a deterministic way. The $P = NP$ problem asks whether every function computable on a non-deterministic machine in polynomial time is computable in polynomial time on ordinary (deterministic) machines. This problem is mentioned in Rabin [1977] and discussed fully by Karp [1972].

Notation

Chapter 1

$R_n$  $n$th register  9
$r_n$  contents of $R_n$  9
$Z(n)$  zero instruction  10
$S(n)$  successor instruction  10
$T(m, n)$  transfer instruction  10
$I(m, n, q)$  jump instruction  11
$r_n' := x$  $r_n$ becomes $x$  10
$P(a_1, a_2, \ldots)$  computation under program $P$  16
$P(a_1, a_2, \ldots)$  the computation stops  16
$P(a_1, a_2, \ldots)$  the computation never stops  16
$P(a_1, a_2, \ldots, a_n)$  the final value in $R_1$ is $b$  17
$\epsilon, \kappa_n$  computable functions  17
$f^*_{a_n}$  $n$-ary function computed by $P$  21
$\alpha_e$  characteristic function of $M$  22

Chapter 2

$U^*$  projection functions  25
$PQ$ or $Q$  concatenation of programs  27
$\rho(P)$  denotes registers affected by $P$  27
$P[l_1, \ldots, l_n = i]$  28
$x - y$  cut-off subtraction  36
\[ s_g(x), s_g(x) \]

Signum functions 36

\[ r(x, y), q(x, y) \]

Remainder and quotient functions 36, 37

\[ u < z < y(\ldots) \]

Least \( z \) less than \( y \) 39

\[ p_n \]

\( n \)th prime number 40

\[ (x)_n \]

Power of \( p_n \) occurring in \( x \) 40

\[ \pi(x, y) \]

A pairing function 41

\[ \mu_y(f(x, y) = 0) \]

Minimalisation operator 43

Chapter 3

\( \mathcal{R}, \mathcal{R}_o \)

(Partial) recursive functions 49

\( \mathcal{P} \mathcal{R} \)

Primitive recursive functions 51

\( \mathcal{T} \mathcal{B} \)

Turing-computable functions 56

\[ Q \]

Obtained by productions in \( Q \) 59

\[ A \]

Post-system \( A \) generates 59

\[ S \]

Strings generated by \( S \) 59

\[ \sigma \]

Coding of a word \( \sigma \) 61

\[ \bar{n} \]

Word representing \( n \) 61

\[ G(f) \]

Graph of \( f \) 62

\( \mathcal{P} \mathcal{B} \)

Post-computable functions 63

Chapter 4

\( \mathcal{S} \)

URM instructions 74

\( \mathcal{P} \)

URM programs 74

\( \gamma \)

Program coding function 75

\[ P_n \]

\( n \)th program = \( \gamma^{-1}(n) \) 75

\[ \phi^{(n)}_a, \phi_a \]

Functions computed by \( P_a \) 76-77

\[ W_a, W_a \]

Domain of \( \phi^{(n)}_a, \phi_a \) 77

\[ E_a \]

Range of \( \phi^{(n)}_a, \phi_a \) 77

Chapter 5

\( \psi_t, \psi_t^{(n)} \]

Universal functions 86

\[ e_n(e, x, t) \]

Configuration code 87

Chapter 6

\[ j_n(e, x, t) \]

Next instruction 87

\[ \sigma_n(e, x, t) \]

State function 87

\[ T_n(e, x, t) \]

Kleene T-predicate 89

\[ \text{Rec}(f, g) \]

Function obtained by recursion from \( f, g \) 91

\[ \text{Sub}(f, g_1, \ldots, g_n) \]

Function obtained by substitution from \( f, g_1, \ldots, g_n \) 91

Chapter 7

\[ \mathcal{Q} \]

Rational numbers 108

\[ \lambda \rightarrow \]

Logical symbols for \( \text{`and', 'implies'} \) 111

\[ 0, 1, \ldots \]

Symbols in a logical language 110

\[ x, y, \ldots \]

Chapter 8

\[ \neg, \lor \]

Logical symbols for \( \text{`not', 'or'} \) 143

\( \mathcal{F} \)

Statements of language \( L \) 144

\( \mathcal{F}, \mathcal{F}' \)

True, false statements of \( L \) 144

\[ \eta_n \]

\( (n + 1) \)th statement of \( \mathcal{F} \) 144

\[ n \in K \]

Formal counterpart of \( n \in K \) 145

\[ \mathcal{F} \]

Provable statements 147

\[ \mathcal{P} \]

\( \{n : n \in K \text{ is provable}\} \) 148

\[ \mathcal{R} \]

\( \{n : n \in K \text{ is provable}\} \) 148

Chapter 9

\[ A \equiv_m B \]

\( A \) is many-one reducible to \( B \) 158

\[ a \equiv_m b \]

Partial order on \( m \)-degrees 162

\[ 0_m \]

\( m \)-degree of recursive sets 163

\[ 0, n \]

\( m \)-degrees of \( \mathcal{Z} \) and \( \mathbb{N} \) 162

\[ 0_m \]

\( m \)-degree of \( K \) 163
\( a \cup b \) least upper bound of degrees \( a, b \) 165
\( O(n) \) oracle instruction 167
\( P^x \) URMO program \( P \) with \( x \) in the oracle 168
\( \mathcal{C}^x \) \( x \)-computable functions 169
\( \mathcal{R}^x \) \( x \)-partial recursive functions 170
\( \phi_n^m, \psi_n^m \) functions computed by \( Q_n^m \) 170-171
\( W_n^x, E_n^x \) domain and range of \( \phi_n^x \) 171
\( \psi^u \) universal function for \( \chi \)-computability 171
\( K^x \) \( = \{ x : x \in W_n^x \} \) 172
\( P^A, \phi^A, \psi^A, W_n^A, E_n^A, K^A \) relativised notions for \( A \)-computability 172
\( A \equiv_T B \) \( A \) is Turing reducible to \( B \) 174
\( \equiv_T \) Turing equivalent 174
d\( T(A) \) Turing degree of \( A \) 175
\( a \equiv b \) partial order on \( T \)-degrees 176
\( 0 \) \( T \)-degree of recursive sets 176
\( 0' \) \( T \)-degree of \( K \) 176
\( A' \) jump of \( A \) 177
\( a' \) jump of \( a \) 177
\( a,b \) \( a, b \) are incomparable degrees 179

Chapter 10
\( \mathcal{F}_n \) \( n \)-ary partial functions 182
\( \theta \) a finite function 183
\( \bar{\theta} \) code for a finite function \( \theta \) 183
\( f_\theta \) least fixed point for \( \Phi \) 192
\( f_\tau \) function defined by program \( \tau \) 196

Chapter 11
\( E_k \) sequence of computable functions enumerated by \( \phi_k \) 208
\( D \) diagonal enumeration 208

Chapter 12
\( i^P_n(x) \) number of steps taken by \( P \) to compute \( f_\tau(x) \) 213
\( i^P_n(x) \) \( i^P_n(x) \) 213
\( S_\alpha, S_\beta \) complexity classes of \( b \) 223, 233

What can computers do in principle? What are their inherent theoretical limitations? These are questions to which computer scientists must address themselves. The theoretical framework which enables such questions to be answered has been developed over the last fifty years from the idea of a computable function: intuitively a function whose values can be calculated in an effective or automatic way.

This book is an introduction to computability theory (or recursion theory as it is traditionally known to mathematicians). Dr Cutland begins with a mathematical characterisation of computable functions using a simple idealised computer (a register machine); after some comparison with other characterisations, he develops the mathematical theory, including a full discussion of non-computability and undecidability, and the theory of recursive and recursively enumerable sets.

The later chapters provide an introduction to more advanced topics such as Gödel's incompleteness theorem, degrees of unsolvability, the Recursion theorems and the theory of complexity of computation. Computability is thus a branch of mathematics which is of relevance also to computer scientists and philosophers. Mathematicians with no prior knowledge of the subject and computer science students who wish to supplement their practical expertise with some theoretical background will find this book of use and interest.

* A reviewer's comment

Dr Cutland has produced here an excellent and much-needed textbook which will undoubtedly help to establish recursion theory as a more widely taught branch of mainstream mathematics.
